Synthesis, structure and dynamics of NHC-based palladium macrocycles†

Rhiann E. Andrew and Adrian B. Chaplin*

A series of macrocyclic CNC pincer pro-ligands based on bis(imidazolium)lutidine salts with octa-, deca- and dodecamethylene spacers have been prepared and their coordination chemistry investigated. Using a Ag₂O based transmetallation strategy, cationic palladium(II) chloride complexes [PdCl{(CNC–(CH₂)ₙ}]-[BARF₄] (n = 8, 10, 12; ArF = 3,5-C₆H₃(CF₃)₂) were prepared and fully characterised in solution, by NMR spectroscopy and ESI-MS, and in the solid-state, by X-ray crystallography. The smaller macrocyclic complexes (n = 8 and 10) exhibit dynamic behaviour in solution, involving ring flipping of the alkyl spacer across the Pd–Cl bond, which was interrogated by variable temperature NMR spectroscopy. In the solid-state, distorted coordination geometries are observed with the spacer skewed to one side of the Pd–Cl bond. In contrast, a static C₂ symmetric structure is observed for the dodecamethylene based macrocycle.

For comparison, palladium(II) fluoride analogues [PdF{(CNC–(CH₂)ₙ}][BARF₄] (n = 8, 10, 12) were also prepared and their solution and solid-state structures contrasted with those of the chlorides. Notably, these complexes exhibit very low frequency ¹⁹F chemical shifts (ca. −400 ppm) and the presence of C–H⋯F interactions (²H)JFC coupling observed by ¹³C NMR spectroscopy). The dynamic behaviour of the fluoride complexes is largely consistent with the smaller ancillary ligand: [PdF{(CNC–(CH₂)₈}][BARF₄] exceptionally shows C₂ᵥ time averaged symmetry in solution at ambient temperature (CD₂Cl₂, 500 MHz) as a consequence of dual fluxional processes of the pincer backbone and alkyl spacer.

Introduction

N-heterocyclic carbenes (NHCs) have quickly emerged as a powerful class of carbon-based ligand in organometallic chemistry and catalysis.¹ With generally stronger σ-donating characteristics and orthogonal steric profiles to widely used phospine ligands, NHCs are rapidly being established as ligands of choice for many transition metal catalysed reactions. Aided by simple and efficient synthetic protocols, intricate polydentate ligand topologies can be readily constructed based on NHC donors.²,³ Building on the flourishing chemistry of phospine-based pincer complexes,⁴ analogous NHC-based tridentate architectures have received considerable attention in particular.²,⁵ Archetypical NHC pincer ligands are derived from bis(imidazol-2-ylidene)-benzene, pyridine, xylene or lutidine frameworks (Fig. 1) and the coordination chemistry of these CNC and CCC pincer ligands has been explored for a variety of late transition metals.²,⁵,⁶ Notably, palladium CNC based complexes have been thoroughly investigated, following seminal work by Crabtree and Piers who demonstrated the application of these species in cross coupling reactions.⁷–¹⁴

The substitution geometries of NHC pincers are well suited to the construction of macrocycles. Principally based on lutidine and xylene backbones, tridentate macrocycles find notable application in supramolecular chemistry; exploiting chemistry of the coordinated metal centre for molecular recognition¹⁵ and the construction of interlocked catenane and rotaxane systems.¹⁶ The vast majority of known CNC and CCC

---

**Fig. 1** NHC-based pincer architectures.
based pincer complexes feature ligands bearing simple alkyl (i.e. Me, t-Bu, Ad) and aryl (e.g. Mes, Dipp) groups. Despite facile synthetic procedures to macrocyclic imidazolium pro-ligands,17 there are very few examples of tridentate NHC-based macrocyclic complexes. Macrocyclic complexes that have been reported are limited to small (e.g. A, 15 membered, Fig. 2)18,19 or very large ring sizes (B and C; 28–38 membered).20,21 Of these systems, tridentate coordination of the macrocycle was observed within B and C, although not in A; the smaller 15 membered ring adopting a bidentate cyclophane geometry2,22 with no pyridine coordination as a consequence of the short butamethylene spacer. Although showing significantly lower catalytic activity than related non-macrocyclic variants,7,10,13,14 both xylene and lutidine based B, promote C–C bond coupling reactions.20

Motivated by the possibility for exploiting their unique steric profile in organometallic chemistry and potential applications as building blocks in interlocking architectures, in this communication we present the synthesis of a range of medium sized (19–23 membered) macrocyclic pro-ligands consisting of bis(imidazolium)lutidine salts with octa-, deca- and dodecamethylene spacers. The coordination chemistry of the corresponding CNC pincer ligands with palladium is detailed, particularly focusing on the effect of the aliphatic chain and ancillary ligands on the structure and dynamics of the resulting macrocyclic complexes, as probed by variable temperature NMR spectroscopy and X-ray diffraction.

Results and discussion

The target macrocyclic pro-ligands [CNC–(CH2)n)]2HBr) (n = 8, 2a; 10, 2b; 12, 2c) were prepared as bromide salts using a straightforward two-step synthesis, involving alkylation of 2,6-bis(bromomethyl)pyridine with bis(imidazole)alkanes 1 in dioxane (Scheme 1). All three intermediate bis-imidazoles (n = 8, 10, 12) were readily prepared following minor adaptions to literature procedures employing commercially available alkyl dibromides.23 The overall synthetic route readily afforded gram scale quantities of 2 in high purity following recrystallisation from acetonitrile–diethyl ether (19–32% overall yields). The salts are notably hygroscopic and best stored and manipulated under a dry inert atmosphere.

The structures of 2 were confirmed by a combination of NMR spectroscopy and ESI-MS, with the latter being particularly diagnostic. Strong dication parent ion signals are observed for each compound: 2a, 175.6207 (calc. 175.6206) m/z; 2b, 189.6361 (calc. 189.6362) m/z; 2c, 203.6521 (calc. 203.6519) m/z. The NMR spectra of 2 in CD2Cl2 exhibit singlet 4H resonances for the methylene bridge at ca. 5.8 ppm, with characteristic 1H and 13C signals of the pre-carbenic centre at ca. 10.7 and 138 ppm, respectively. The remaining features of the spectroscopic data fully corroborate the structures of 2 and are otherwise unremarkable. Satisfactory microanalysis was obtained for all the macrocycles, and the structure of 2b was further confirmed by X-ray crystallography (ESI†).

Typically, coordination of CNC pincers to palladium has been achieved through reaction of the corresponding imidazolium pro-ligands with [Pd(OAc)2] in DMSO at elevated temperatures.5 With a view of developing a more general procedure for the coordination of pro-ligands 2 with transition metals, we have adapted Ag2O based transmetallation strategies previously employed by Youngs, Danopoulos and Cavell for this initial work involving palladium.9–11 This procedure is outlined in Scheme 2, and involves reactions of 2 with Ag2O and Na[BAR4] (ArF = 3,5-C6H4(CF3)2) in CH2Cl2, followed by
subsequent addition of [PdCl₂(NCPh)₂] as a source of palladium(n) halide – all carried out at room temperature. Using this convenient and mild procedure, macrocyclic palladium complexes [PdCl₂(CNC(CH₂)n)] [BARF₄] (n = 8, 3a; 10, 3b; 12, 3c) were prepared with moderate-to-good isolated yields of 31% (n = 8), 55% (n = 10) and 58% (n = 12), following purification on silica and recrystallisation. [PdCl₂(NCMMe)₂] can also be used as the palladium(n) halide source, but gave no significant improvements in yield. Complexes 3 are air stable both in solution and the solid state; dissolving readily in CH₂Cl₂, CHCl₃, Et₂O and MeCN. No attempts were made to isolate the corresponding intermediate silver complexes, although we note that the incorporation of the [BARF₄]⁻ anion appears to plays an import role in solubilising these species throughout the procedure.

The palladium complexes 3 were fully characterised by NMR spectroscopy, ESI-MS and elemental analysis. Coordination of the ligand was confirmed through the presence of strong parent ion peaks with the expected isotope distributions in mass spectra [3a, 490.0993 (calc. 490.0989) m/z; 3b, 518.1308 (calc. 518.1303) m/z; 3c, 546.1616 (calc. 546.1617) m/z]. H and ¹³C NMR spectra further corroborate the structures of the compounds, which all exhibit approximate C₂ symmetry in solution at room temperature (CDCl₃, and CD₂Cl₂, 400 or 500 MHz). The binding of the ligand through carbene donors is established by the absence of the distinctive high frequency imidazolium proton resonances of 2 and significant ¹³C shifts of the carbene centre from ca. 138 to 163 ppm. These carbene resonances differ only marginally within the series of complexes, although a positive correlation with increasing frequency and macrocycle size is noted, i.e. 162.4 (3a), 163.3 (3b), 164.5 (3c) ppm. All values are in good agreement with that observed for the non-macrocyclic analogue [PdCl₂(CNC–Me)]⁺ D (164 ppm, Scheme 2).¹³ Complexes 3 show interesting dynamic behaviour in solution and these features are discussed below in detail.

Crystal structures of all three palladium macrocycles were obtained, revealing significant structural differences between the complexes (Fig. 3 and Table 1). Tridentate coordination of the macrocyclic ligand is observed for each complex, with the pincer moiety adopting a characteristic twisted pseudo C₂ conformation, where the pyridine (ca. 40°) and imidazolylidene rings are angled out of the coordination plane as a consequence of the methylene bridges.⁹–¹³ Associated Pd1–N1 (ca. 2.1 Å), Pd1–C (ca. 2.0 Å) and Pd1–Cl1 (ca. 2.3 Å) distances closely match those found in other related palladium CNC pincer complexes, as exemplified by comparison to D (Table 1).¹³ The principle differences between the structures are manifested in the conformation of the alkyl spacer, which is skewed to one side of the Pd–Cl bond for the shorter spacers (n = 8 and 10) as a consequence of the steric interactions between the spacer and the chloride ligand. This interaction distinctly leads to distortions of the metal coordination geometry which are most pronounced for 3a, with C7–Pd1–C11 and especially N1–Pd1–Cl1 angles deviating dramatically from 180° [168.82(7) and 163.39(4)°]. With the largest dodecamethylen spacer, 3c adopts an overall pseudo C₁ geometry, with the coordinated chloride ligand fully enclosed within the macrocycle cavity; the C7–Pd1–C11 and N1–Pd1–Cl1 angles are essentially linear [172.8(6) and 176.2(3)°] as observed for non-macrocyclic D [173.60(7) and 178.19(3)°].¹³ Related palladium chloride CNC pincer complexes bearing bulky ‘Bu, Mes and Dipp substituents retain N–Pd–Cl bond angles of effectively 180°.⁸–¹⁰ Distortion from linearity is uncommon within known palladium(n) square planar complexes (following inspection of CSD metrics), although complexes with angles down to 150° are known.²⁴

To investigate the apparent inconsistency between the solution (C₂ symmetry) and solid-state (C₁ symmetry) structures of 3a and 3b, we turned to variable temperature NMR measurements. The fluxional behaviour of CNC based pincer complexes [PdX(CNC–Me)]⁺ D–F (Scheme 2) has previously been investigated in detail by Crabtree and co-workers.¹²,¹⁴ These complexes undergo atropisomerisation between left and right-handed C₂ conformations with a free energy barrier of 60.0 kJ mol⁻¹ for [D]Cl (CD₂Cl₂, Tc = 303 K for the methylene bridge protons).¹⁵ The rate of this process is highly dependent on the halide–anion combination. Increased activation barriers are observed for complexes containing the weakly coordinating OTs⁻ anion ([D]OTs, ΔG‡(CDCl₃) = 66.0 kJ mol⁻¹) and along the series: [F]Cl, [E]Br, [D]Cl [ΔG‡(CDCl₃)] = 41.9, 52.9 and 59.3 kJ mol⁻¹. On the basis of these observations and supporting computational work, a two-step interconversion mechanism involving dissociation of the pyridine group and coordination of the counter anion was proposed. Atropisomerisation (ΔG‡(CDCl₃) = 57–59 kJ mol⁻¹) is also observed in the macrocyclic complexes [B]Br [Fig. 2, E = N] although only very small changes in barrier height are observed in comparison to...
the directly related $^n$Bu substituted analogue $[\text{PdBr(CNC–}^n\text{Bu)}]$Br ($\Delta G^i(\text{CDCl}_3) = 57.4$ kJ mol$^{-1}$) - indicating no significant macrocyclic effect.\textsuperscript{20} Remarkably, no dynamic behaviour of the pincer coordination geometry is observed for $3$ with the methylene bridge protons diastereotopic in CD$_2$Cl$_2$ solution (500 MHz) up to 308 K (i.e. $\Delta G^i \gg 62$ kJ mol$^{-1}$). This is consistent with the non-coordinating nature of the $[\text{BARF}_4]$ anion\textsuperscript{26} and the calculated gas-phase barrier of D of 73.2 kJ mol$^{-1}$.\textsuperscript{12}

In agreement with the solid-state structure, $3c$ retains $C_2$ symmetry from 200–298 K in CD$_2$Cl$_2$ solution (500 MHz), further confirming the good fit of the coordinated chloride ligand within the cavity of the macrocyclic ligand. For complexes $3a$ and $3b$, variable temperature NMR experiments demonstrate ring flipping of the macrocycle across the palladium chloride bond. This fluxional process mediates an atropisomerisation between skewed $C_1$ symmetric confirmations observed in the solid-state (Fig. 3) and leads to the time averaged $C_3$ symmetry in solution at room temperature. For $3a$, the slow exchange limit for this process is reached at 200 K in CD$_2$Cl$_2$ (500 MHz), with the $^1$H NMR spectrum showing three pyridine and four imidazolylidene resonances together with pairs of diastereotopic methylene bridge (pyC–H$_2$) and N–CH$_2$ signals (Fig. 4). Simulation\textsuperscript{27} of the $^1$H NMR data over the temperature range 185 to 298 K allowed rate data to be extracted for the exchange process, leading to values of $\Delta H^\ddagger = 43 \pm 4$ kJ mol$^{-1}$, $\Delta S^\ddagger = -7 \pm 17$ J mol$^{-1}$ K$^{-1}$ and $\Delta G^\ddagger(298 \text{K}) = 45 \pm 9$ kJ mol$^{-1}$ following an Eyring analysis (see ESI†).

In line with the longer alkyl spacer, the fluxional process in $3b$ is much faster than $3a$: the exchange could not be completely frozen out, even upon cooling to 185 K, although the barrier for this process can be approximated at $\Delta G^\ddagger = 37$ kJ mol$^{-1}$ from signal coalescence at low temperature.\textsuperscript{28}

To further investigate the dynamics of the macrocyclic ligands, metathesis of the chloride ligand with the smaller fluoride ligand was targeted. This was achieved by reactions of $3$ with excess AgF in acetonitrile to afford the palladium(II) fluoride complexes $[\text{PdF(CNC–}(CH_2)_n\text{)}][\text{BARF}_4]$ ($n = 8, 4a; 10, 4b; 12, 4c$) with good to moderate isolated yields of 45–88%
Unlike their palladium(II) chloride analogues, the fluorides are markedly water sensitive and degrade readily on silica. Facile loss of the fluoride ligand is also apparent by ESI-MS and only fragment ion derivatives can be observed. Although many examples of palladium fluoride complexes containing phosphine and nitrogen based donor ligands are known, to the best of our knowledge no NHC based analogues have been reported. The formation of 4 are readily corroborated by $^1$H, $^{13}$C and $^{19}$F NMR spectroscopy and elemental analysis. The coordinated carbene centres are observed as broad singlets at ca. 165 ppm by $^{13}$C NMR spectroscopy to slightly higher frequency than observed in 3, while $^{19}$F NMR spectra reveal characteristically low frequency Pd(II) fluoride resonances at ca. −400 ppm. $^{19}$F chemical shifts of this magnitude are uncommon, although notably the palladium PNP pincer G (Scheme 3) has a $^{19}$F NMR shift of −414.3 ppm for the coordinated fluoride ligand.

Like its chloride analogue, temperature invariant $^1$H NMR spectra of 4c demonstrate the adoption of $C_2$ symmetry in solution. For the smaller 4b, a very low energy fluxional process can be detected only by cooling to 185 K, where the onset of coalescence is noted for one of the $N$-CH$_3$ resonances. In comparison to 3b, the interconversion barrier for 4b must be considerably less as at 185 K the slow exchange limit is essentially reached for all signals of 3b. Given the large $\Delta\nu$ possible for the $N$-CH$_3$ shifts it is difficult to approximate the barrier, although we estimate a value of $\Delta G^\ddagger$ ≤ 34 kJ mol$^{-1}$ (based on $\Delta\nu = 600$ Hz from 3a). The solid-state structure of 4b shows a more symmetric structure than 3b (Fig. 5), with the N1–Pd1–F1 angle approaching 180° [175.77(7) cf. 166.29(5)° for 3b], although meaningful conclusions from this observation are difficult due to crystal packing effects. Notably the cations in 4b pack with relatively close Pd1–Pd1’ and Pd1–F1’ distances of 4.3357(7) and 3.866(2) Å, respectively. A further interesting feature of note is the presence of weak $N$-CH–H⋯F interactions, which were detected by carbon–fluorine coupling for both 4b and 4c ($^{2}$J$_{FC} = 6$ Hz, 298 K). These $^{2}$J$_{FC}$ values and the corresponding interatomic distances observed in

(Scheme 3).
solid-state structure of 4b [C–F = 2.968(3), 3.146(3) Å], are fully consistent with other C–H⋯F interactions reported in the literature.\textsuperscript{32}

In solution, 4a is highly fluxional. At 298 K in CD\textsubscript{2}Cl\textsubscript{2} (500 MHz), \textit{C\textsubscript{2v}} symmetry is observed indicating an atropoisomerisation mechanism involving dynamics of both the pincer and octamethylene spacer. Upon cooling the sample to 225 K onset of decoalescence of the methylene bridge and N–CH\textsubscript{2} protons was observed, while those of the imidazolylidene remained relatively sharp. Further cooling to 185 K led to broadening of the later signals, although the slow exchange limit was not reached (precluding accurate simulation). These observations support a dual fluxional process involving low energy flipping of the octenyl linker (\(\Delta G^\ddagger \leq 34 \text{ kJ mol}^{-1}\)) and higher energy pincer twisting (\(\Delta G^\ddagger \sim 43 \text{ kJ mol}^{-1}\)). The latter process is characteristic of D–F, with the approximate barrier height of 43 \text{ kJ mol}^{-1} being broadly similar to that calculated for dicaticionic [Pd(CNC–Me)\textsubscript{2}]+ (\(\Delta G^\ddagger = 47.8 \text{ kJ mol}^{-1}\))\textsuperscript{12} and suggestive of fluoride ligand dissociation (promoted by macrocycle induced steric pressure). Although we could obtain a solid-state structure of 4a, somewhat inline with its highly fluxional solution characteristics, it has two crystallography independent cations both with extensively disordered macrocycle geometries (see ESI\textsuperscript{1}). However, what is clear from the structure is that the octamethylene group is skewed to one side of the palladium(u) fluoride bond (as with 3a and 3b) and the N–Pd–F angle deviates from linearity (ca. 172\(^\circ\)). The shorter macrocycle linker also results in further close C–H⋯F interactions, with coupling at 1,8– (\(2^\text{H}J_{\text{FC}} = 14 \text{ Hz}\)) and 4,5– (\(2^\text{H}J_{\text{FC}} = 6 \text{ Hz}\)) positions along the octamethylene group resolved by \textsuperscript{13}C NMR spectroscopy.

Summary

A series of macrocyclic CNC pincer pro-ligands have been prepared incorporating simple alkyl spacers, resulting in 19, 21 and 23 membered ring systems (2). The coordination chemistry of these pro-ligands has been explored, and a series of cationic palladium(u) chloride (3) and fluoride (4) complexes have been synthesised and fully characterised in solution and the solid-state. The larger macrocyclic complexes, containing dodecamethylene spacers, exhibit static \textit{C\textsubscript{2}} symmetric structures with the coordinated halogen ligands lying within the macrocyclic cavity. As the ring size is reduced, increasing dynamic behaviour is observed in solution, with the spacer undergoing ring flipping across the palladium halogen bond, and is most pronounced with the larger chloride ancillary ligand (Table 2). The atropoisomeration of the smaller macrocyclic complexes is also manifested in their solid-state structures, with significant distortions from the expected square planar geometries and skewing of the alkyl spacers to one side of the palladium–halogen bonds observed. The dodecamethylene based CNC pincer ligands accommodate the coordinated metal–ligand moiety most readily and appear most suitable for subsequent applications in organometallic chemistry and as building blocks for interlocking architectures: the organometallic chemistry of other late transition complexes bearing this ligand is currently being explored.\textsuperscript{33}

Experimental

General considerations

Manipulations were performed under an inert atmosphere, using Schlenk (nitrogen) and glove box (argon) techniques unless otherwise stated. Glassware was oven dried and flame dried under vacuum prior to use. Anhydrous solvents (<0.005% H\textsubscript{2}O) were purchased from ACROS or Aldrich and used as supplied: MeCN, CH\textsubscript{2}Cl\textsubscript{2}, CHCl\textsubscript{3}, THF, 1,4-dioxane, pentane and Et\textsubscript{2}O. CD\textsubscript{2}Cl\textsubscript{2} was dried over CaH\textsubscript{2}, vacuum-distilled and stored under an atmosphere of argon. CDCl\textsubscript{3} (for NMR characterisation of 4) was dried over 3 Å molecular sieves, vacuum-distilled and stored over sieves. Na[BA\textsubscript{2}F\textsubscript{4}]\textsubscript{34} and [Rh(CO)\textsubscript{2}Cl\textsubscript{2}]\textsubscript{35} were synthesised using literature procedures. Bis-imidazoles 1 were prepared by adaptations of literature procedures and are fully detailed in the ESI.\textsuperscript{+23} [PdCl\textsubscript{2}(NCPh)\textsubscript{2}], [PdCl\textsubscript{2}(NCMe)\textsubscript{2}], Ag\textsubscript{2}O, AgF, 2,6-bis(bromomethyl)pyridine, and dibromoalkanes are commercial products and were used without further purification. NMR spectra were recorded on Bruker DPX-400, AV-400 and DRX-500 spectrometers at 298 K unless otherwise stated. Chemical shirts are quoted in ppm and coupling constants in Hz. ESI-MS were recorded on a Bruker MaXis mass spectrometer. Microanalyses were performed at the London Metropolitan University by Stephen Boyer.

Preparation of pro-ligands (2)

General procedure. To refluxing 1,4-dioxane (150 mL), equimolar solutions of 2,6-bis(bromomethyl)pyridine and bis-imidazole 1 in THF (ca. 0.075 M, dried over 3 Å molecular sieves) were simultaneously added dropwise over 30 minutes. The resulting reaction mixture was refluxed for 16 hours, cooled to approx. 50 °C and the solvent removed in vacuo. The resulting off-white residue was extracted with MeCN (ca. 200 mL) with vigorous stirring. The MeCN solution was filtered, concentrated and excess Et\textsubscript{2}O added to precipitate the product. The product was isolated by filtration and washed with excess Et\textsubscript{2}O.

Table 2: Summary of the structure and dynamics of 3 and 4
2a: following the general procedure using 2,6-bis(bromo-methyl)pyridine (0.79 g, 2.98 mmol) and 1a (0.73 g, 2.98 mmol), the product was obtained as an off-white foam. Yield: 0.47 g (31%).

1H NMR (400 MHz, CDCl3) δ 10.55 (app. t, J = 2, 2H), 8.00 (app. t, J = 2, 2H), 7.82 (dd, J_HH = 8.4, 7.0, 1H), 7.72 (app. d, J = 8, 2H), 7.40 (app. t, J = 2, 2H), 5.82 (s, 4H), 4.42 (t, J_HH = 4.4, 4H), 1.88 (app. pentent, J = 7, 4H), 1.32–1.41 (m, 4H), 1.18–1.28 (m, 4H). 13C{1H} NMR (101 MHz, CDCl3) δ 153.6, 139.5, 137.9, 124.6, 124.1, 54.2, 50.1, 29.6, 27.5, 24.7. ESI-MS (CH3Cl2, 180 °C, 3 kV) positive ion: 175.6206 m/z, [M]2+ (calc. 175.6206). Anal. Calcd for C22H26ClF24N4Pd (536.52 g mol⁻¹): C, 25.0. Found: C, 25.2.

A mixture of {[PdCl2(NCPh)2]} (1.03 g, 1.03 mmol) and Na[BArF4] (CH2Cl2, 180 °C, 3 kV) positive ion: 203.6519 m/z. RC{27} (calc. 203.6519). Anal. Calcd for C22H26ClF24N4Pd {536.52 g mol⁻¹}: C, 52.92; H, 6.57; N, 12.34. Found: C, 52.82; H, 6.53; N, 12.17.

Preparation of [PdCl(CNC(CH3)2)]2[BArF4] (3)

General procedure. A mixture of 2 (1 equiv.), Ag2O (1 equiv.) and Na[BArF4] (1 equiv.) in CH2Cl2 (3 mL) were stirred in the absence of light for 16 hours. A solution of [PdCl2(NCPh)2] (1 equiv.) in CH2Cl2 (ca. 3 mL) was added and the suspension stirred for a further 5 hours. The solution was filtered and the filtrate reduced to dryness in vacuo to afford the crude product. Purification was achieved by passing through a silica pad using CH2Cl2 eluent.

3a: following the general procedure using 2a (0.060 g, 0.117 mmol) and subsequent recrystallisation from CHCl3–pentane, the product was obtained as pale-yellow crystalline solid. Yield: 0.049 g (31%).

1H NMR (400 MHz, CDCl3) δ 7.71 (t, J_HH = 7.7, 1H, py), 7.66–7.71 (m, 8H, Ar²), 7.49 (br, 4H, Ar²), 7.38 (d, J_HH = 7.7, 2H, py), 6.94 (d, J_HH = 1.9, 2H, imid), 5.39–5.51 (m, 2H, N–CH3), 5.34 (d, J_HH = 15.3, 2H, pyCH2), 5.08 (d, J_HH = 15.3, 2H, pyCH2), 3.80 (dt, J_HH = 13.3, J_HH = 6.6, 2H, N–CH3), 2.79 (br, 2H, CH2), 1.98–2.14 (m, 2H, CH2), 1.72–1.86 (m, 2H, CH3), 1.60–1.72 (m, 2H, CH3), 1.41–1.54 (m, 2H, CH2), 1.12–1.25 (m, 2H, CH2). 13C{1H} NMR (101 MHz, CDCl3) δ 162.4 (s, Pd–C), 161.8 (q, J_CB = 50, Ar²), 154.7 (s, py), 141.7 (s, py), 134.9 (s, Ar²), 129.1 (qq, J_FC = 32, J_CB = 3, Ar²), 125.7 (s, py), 124.6 (q, J_FC = 273, Ar²), 123.7 (s, imid), 120.4 (s, imid), 117.7 (pentent, J_FC = 4, Ar²), 56.2 (s, pyCH2), 50.0 (s, N–CH3), 31.1 (s, CH2), 26.5 (s, CH3). ESI-MS (CH3CN, 180 °C, 3 kV) positive ion: 139.5, 137.9, 124.6, 122.1, 54.2, 50.1, 29.6, 27.5, 24.7. ESI-MS (CH3CN, 180 °C, 3 kV) positive ion: 139.5, 137.9, 124.6, 122.1, 54.2, 50.1, 29.6, 27.5, 24.7.
Preparation of $\text{[PdF(CNC-(CH$_2$_)$_n$)]$\text{[BARF$_{4}$]}$} (4)$

**General procedure.** To a solution of AgF in MeCN (3 mL) was added a solution of 3 in MeCN (2 mL). The resulting suspension was stirred in the dark at room temperature for 1–3 hours. The solvent was removed in vacuo and the product precipitated with CHCl$_3$ through celeite (Pasteur pipette, 3 cm).

4a: following the general procedure using AgF (0.023 g, 0.181 mmol) and 3a (0.050 g, 0.037 mmol) - stirred for 1 hour, the product was obtained as an off-white solid. Yield: 0.030 g (61%).

**$^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.67–7.72 (m, 9H, py + Ar$^+$), 7.49 (br, 4H, Ar$^+$), 7.35 (d, $^3$J$_{HF}$ = 7.8, 2H, py), 6.95 (d, $^3$J$_{HF}$ = 1.8, 2H, imid), 6.90 (d, $^3$J$_{HF}$ = 1.8, 2H, imid), 5.23 (s, 4H, pyCH$_2$), 4.31 (app. t, $^4$J$_{HF}$ = 7, 4H, N-CH$_2$), 2.04–2.15 (m, 4H, CH$_2$), 1.42–1.53 (s, 8H, CH$_2$).

$^{19}$F NMR (377 MHz, CDCl$_3$) $\delta$ -62.38 (s, ArF), -392.08 (s, Pd-F).

$^{13}$C($^1$H) NMR (101 MHz, CDCl$_3$) $\delta$ 164.8 (s, Pd-C), 161.8 (q, $^2$J$_{FC}$ = 50, Ar$^+$), 154.5 (s, py), 141.2 (s, py), 134.9 (s, Ar$^+$), 129.1 (qq, $^2$J$_{FC}$ = 32, $^3$J$_{FC}$ = 3, Ar$^+$), 126.2 (s, py), 124.6 (q, $^2$J$_{FC}$ = 273, Ar$^+$), 123.2 (s, imid), 119.7 (s, imid), 117.7 (pentet, $^3$J$_{FC}$ = 4, Ar$^+$), 55.8 (s, pyCH$_2$), 50.0 (d, $^3$J$_{FC}$ = 14, N-CH$_2$), 30.2 (s, CH$_2$), 26.0 (s, CH$_2$), 25.5 (d, $^3$J$_{FC}$ = 6, CH$_2$).

**ESI-MS** (CH$_2$Cl$_2$, 180 °C, 3 kV) positive ion: 500.1283 m/z (100%), [M + F$^+$/[CH$_3$COO$^-$]) (calc. 500.1278); 456.1377 m/z (35%), [M - F$^+$/[HCOO$^-$]) (calc. 456.1382).

**Anal.** Caled for C$_{37}$H$_{36}$Br$_2$N$_6$Pd: C 57.5, H 4.9 (found: C 57.3, H 4.4).

4b: following the general procedure using AgF (0.019 g, 0.150 mmol) and 3b (0.056 g, 0.041 mmol) - stirred for 3 hours, the product was obtained as a white solid (0.049 g, 88%).

$^1$H NMR (400 MHz, CDCl$_3$) $\delta$ 7.67–7.71 (m, 8H, Ar$^+$), 7.66 (t, $^3$J$_{HF}$ = 7.8, 1H, py), 7.49 (br, 4H, Ar$^+$), 7.35 (d, $^3$J$_{HF}$ = 7.8, 2H, py), 6.98 (d, $^3$J$_{HF}$ = 1.8, 2H, imid), 6.90 (d, $^3$J$_{HF}$ = 1.8, 2H, imid), 5.60 (d, $^3$J$_{HF}$ = 15.2, 2H, pyCH$_2$), 4.97 (d, $^3$J$_{HF}$ = 15.2, 2H, pyCH$_2$), 4.66 (td, $^3$J$_{HF}$ = 12.5, $^3$J$_{HH}$ = 3.9, 2H, N-CH$_2$), 3.71 (td, $^3$J$_{HF}$ = 12.5, $^3$J$_{HH}$ = 5, 2H, N-CH$_2$), 2.00–2.15 (m, 2H, CH$_2$), 1.34–1.81 (m, 12H, CH$_2$), 0.97–1.12 (m, 2H, CH$_2$).

$^{19}$F NMR (377 MHz, CDCl$_3$) $\delta$ -62.38 (s, ArF), -399.89 (s, Pd-F).

$^{13}$C($^1$H) NMR (101 MHz, CDCl$_3$) $\delta$ 165.0 (s, Pd-C), 161.8 (q, $^2$J$_{FC}$ = 50, Ar$^+$), 155.6 (s, py), 141.2 (s, py), 134.9 (s, Ar$^+$), 129.1 (qq, $^2$J$_{FC}$ = 32, $^3$J$_{FC}$ = 3, Ar$^+$), 122.3 (s, imid), 117.7 (pentet, $^3$J$_{FC}$ = 4, Ar$^+$), 55.6 (s, pyCH$_2$), 50.6 (d, $^3$J$_{FC}$ = 6, N-CH$_2$), 30.4 (s, CH$_2$), 27.0 (s, CH$_2$), 25.6 (s, CH$_2$), 24.5 (s, CH$_2$).

ESI-MS (CH$_2$Cl$_2$, 180 °C, 3 kV) positive ion: 542.1762 m/z (100%), [M - F$^+$/[CH$_3$COO$^-$]) (calc. 542.1747); 528.1604 m/z (10%), [M - F$^+$/[HCOO$^-$]) (calc. 528.1591).

**Anal.** Caled for C$_{37}$H$_{39}$BF$_2$Cl$_2$N$_5$Pd (1366.15 g mol$^{-1}$): C, 48.35; H, 3.17; N, 5.13. Found: C, 48.45; H, 3.11; N, 5.17.

4c: following the general procedure using AgF (0.022 g, 0.173 mmol) and 3c (0.050 g, 0.035 mmol) - stirred for 1 hour, the product was obtained as an oil that was washed with pentane and dried to give a white foam (0.022 g, 45%).

---

This table includes crystallographic data for compounds 2b, 3a, and 4b, detailing lattice parameters, density, and other structural parameters. The data is indicative of the crystalline structure of these compounds, providing insights into their molecular organization and packing within the crystal lattice.
Variable temperature NMR experiments

All measurements were performed using a DRX-500 spectrometer. Samples [0.014 M in CDCl₃] were prepared in J. Youngs NMR tubes under inert atmosphere and equilibrated at each temperature inside the spectrometer for 10 minutes prior to data acquisition. Spectra and selected data are compiled in the ESI.†

Crystallography

Crystallographic data for 2b, 3 and 4 are summarised in Table 3. Full details about the collection, solution and refinement are documented in the CIF, which have been deposited with the Cambridge Crystallographic Data Centre under CCDC 961289–961294.

Acknowledgements

We thank the University of Warwick (R.E.A.) and the Royal Society (A.B.C.) for financial support.

References

Preliminary catalytic data for 3c (Heck reaction) is detailed in the ESI.†
