Achiral meteoritic amino acids, glycine and α-methylalanine, with hydrogen isotope (D/H) chirality, act as the source of chirality in asymmetric autocatalysis with amplification of ee to afford highly enantioenriched 5-pyrimidyl alkanols.

One of the most fascinating subjects about the prebiotic world is the origin of homochirality, as in l-amino acids and d-sugars. According to the theory of the extraterrestrial origin of biological homochirality, the amino acids in meteorites have been considered to play an important role in molecular evolution because a variety of prebiotic organic molecules, especially L-enriched amino acids with only slight enantiomeric excess (ee), have been identified. Their stable-isotope enrichment (2H, 13C and 15N) supports an extraterrestrial origin for these chiral amino acids.

On the other hand, meteorites also include achiral amino acids such as glycine and α-methylalanine that have also been identified as isotopically enriched relative to terrestrial compounds. The δD value of Vienna standard mean ocean water of meteoritic glycine and α-methylalanine appeared to be 399% and 3097%, in contrast to the terrestrial biogenic compounds, which range from 350% to 50%. Although glycine and α-methylalanine composed of 1H are achiral, this is not the case of meteoritic compounds because their hydrogen isotope ratio is high and should include the isotopically chiral components. Deuteration of the methylene group of glycine and one methyl group of α-methylalanine produces the hydrogen isotopically chiral compounds glycine-α-d1 and α-methyl-α-d2-alanine (Fig. 1).

To the best of our knowledge, there are no reports on the analysis of isotopic chirality of achiral meteoritic amino acids. Analysis of the isotopic chirality in meteoritic achiral molecules is an important subject to help understand the possible role of these compounds as the origin of chirality. In addition, it may expand research on the pathway by which chirality and isotopic enrichment are produced in the meteoritic compounds in the universe.

Fig. 1 Generation of chirality by the deuterium substitution of enantiotopic hydrogen in glycine and α-methylalanine.

Although there are a few reports on asymmetric reactions,1c,5 and separation6 induced by hydrogen isotope chirality, unlike usual chiral compounds the recognition of the enantiomers solely as a result of isotope labeling still remains difficult. Thus, the development of a highly sensitive method for the detection of isotopic chirality in meteorite organic compounds, especially amino acids, which are identified in carbonaceous chondrites with an achiral framework and isotopic enrichment, is a challenging subject.

We and others have extensively studied asymmetric autocatalysis with amplification of ee.7–11 We have also reported that the external chiral initiator,12 such as chiral natural amino acids,12c in the reaction of pyrimidine-5-carbaldehyde and diisopropylzinc (i-Pr2Zn) controls the absolute configuration of the produced 5-pyrimidyl alkanols and that the ee of the produced pyrimidyl alkanols is high, in conjunction with asymmetric autocatalysis. Chiral deuterated primary alcohols and carbon isotopically chiral compounds can work as chiral triggers of this autocatalytic amplification of ee.13

We report here that the isotopically chiral glycine-α-d1 (1)14 and α-methyl-d1-alanine (2)15 induce the enantioselective addition of i-Pr2Zn to pyrimidine-5-carbaldehyde 3 to afford, in combination with asymmetric autocatalysis, pyrimidyl alkanol 4 with significantly high ee. The absolute configuration of the corresponding alkanol 4 was controlled efficiently by the chirality resulting from hydrogen isotope substitution of 1 and 2 (Scheme 1). Hydrogen isotope enantiomers of compounds 1 and 2 were synthesized by a previously reported method14,15 and the ee was determined from the 1H NMR spectrum of the camphanyl amide of 1 and the α-methoxy-α-(trifluoromethyl)phenyl-acetamide (MTPA amide) of 2 by the diastereomer method. The results of asymmetric autocatalysis triggered by isotopically chiral amino acids are summarized in Table 1. When the i-Pr2Zn addition was performed in the presence of the (S)-glycine-α-d1 (1) with an ee of 93%, the (S)-5-pyrimidyl alkanol 4 was obtained in a 94% yield with an ee of 96%.
The enantioselectivity and stereochemical correlation between the hydrogen isotope chirality of achiral amino acids, *i.e.*, glycine 1 and α-methylalanine 2, and absolute configuration of the subsequent pyrimidyl alkanol 4.

* The ee of 1 and 2 were determined from the 1H NMR spectrum of the camphanyl amide of 1 and the MTPA amide of 2. ^ Isolated yield. ^ The ee was determined using HPLC employing a chiral stationary phase. ^ The molar ratio was 1/3/i-Pr2Zn = 0.05/1.05/2.2. The aldehyde 3 and i-Pr2Zn were added in three separate portions. Experimental details are as follows (entry 1): i-Pr2Zn (0.15 mL of 1 M methylecylexhane (MCH) solution, 0.15 mmol) was added to (S)-1 (3.8 mg, 0.05 mmol) and the mixture was stirred for 12 h at room temperature. After the addition of i-Pr2Zn (0.5 mL of 1 M MCH solution, 0.5 mmol) at 0 °C, a MCH (2.0 mL) solution of 3 (9.4 mg, 0.05 mmol) was added over a period of 1 h and the mixture was stirred for 6 h at 0 °C. After toluene (3.2 mL) and i-Pr2Zn (0.4 mL of 1 M toluene solution, 0.4 mmol) were added, the reaction mixture was stirred for 10 min. Then, a toluene (1.5 mL) solution of 3 (37.6 mg, 0.2 mmol) was added over a period of 1 h at 0 °C, and the mixture was stirred for 2 h. Moreover, after toluene (14.4 mL) and i-Pr2Zn (1.6 mL of 1 M toluene solution) were added and the mixture was stirred for 10 min, a toluene (4.0 mL) solution of 3 (150.6 mg, 0.8 mmol) was added over a period of 1 h. After stirring for 1 h, the reaction was quenched with 1 M aqueous hydrochloric acid (5 mL) at 0 °C. After neutralization with saturated aqueous sodium hydrogen carbonate (15 mL), the mixture was filtered through Celite, and the filtrate was extracted with ethyl acetate. The combined organic fractions were dried over anhydrous sodium sulfate and evaporated in vacuo. Purification of the residue using silica gel thin layer chromatography (hexane-ethyl acetate = 2/1, v/v) gave (S)-4 (229 mg, 0.9849 mmol, 96% ee) in 94% yield. ^ The molar ratio was 2/3/i-Pr2Zn = 0.075/0.625/1.35. The aldehyde 3 and i-Pr2Zn were added in four separate portions. Each pair of reactions (9/13 and 10/14) was performed using the same apparatus to exclude any effect other than that of isotopically chiral amino acid 2.

The results were reproducible. Thus, (S)-4 with an ee of 95% was obtained in the presence of (S)-1 (entry 2). The asymmetric autocatalysis using (S)-1 with 94% ee prepared in a different batch supported the reproducibility; that is, (S)-1 induces the formation of (S)-4 with high ee (entries 3, 4). On the other hand, in the presence of the (R)-1 instead of the (S)-1 enantiomer, the reaction between aldehyde 3 and i-Pr2Zn always gave (R)-4 with an ee of 91–93% in a yield of 90–94% (entries 5–8). These results clearly exhibit the correlation between the chirality of the glycine-α-δ (1) and the absolute configuration of the resulting alkanol 4.

Next, we examined the highly enantioselective addition of i-Pr2Zn to pyrimidine-5-carbaldehyde 3 using the (R)- and (S)-α-methyl-δ3-alanine (2). In the presence of (R)-α-methyl-δ3-alanine (2), (S)-5-pyrimidyl alkanol 4 was induced, and was obtained with an ee of 96–99% (series II, entries 9–12). On the other hand, in the presence of (S)-2, the reaction between aldehyde 3 and i-Pr2Zn always gave (R)-alkanol 4 with an ee of...
96–99% in a yield of 84–99% (entries 13–16). To exclude any effect other than that of the α-methyl-d_{3}-alanine (2), both reactions (entries 9, 13 and 10, 14) induced by (R)- and (S)-2 were performed using the same apparatus to give the (S)- and (R)-alkanols 4, respectively.

The chirality of these enantiomers is mainly due to the very small difference between the lengths of the C–D and C–H bonds. The high ee observed in the above asymmetric reactions was performed using the same apparatus to give the (S)- and (R)-alkanols 4, respectively.
