An octadentate cyclen-based europium complex with amide and hydroxalkyl pendent moieties exhibits pH dependent ligand denticity associated with anion recognition. Unusually high hydration numbers are determined for ortho-phthalate ternary outer-sphere complexes for which modulation of lanthanide-based luminescence is observed.

The design of chelating anion sensors using cyclen-based europium complexes has focussed upon heptadentate cyclen chelates bearing three pendent side-arms. In these complexes the europium square-antiprismatic coordination polyhedron includes two aqua ligands. Anion recognition events require selective displacement of aqua ligands upon binding of the anion to the metal centre. Biologically relevant dicarboxylate anions form five- or six-membered chelate rings upon binding to the metal centre with concomitant modulation of sensitised lanthanide emission. However, recognition of aromatic dicarboxylate anions is reported to be more effective using terbium[III] analogues.

Enhanced luminescence has been observed upon binding of the \(\text{H}_{2}\text{N}\text{N}-\text{dimethylaminocarboxylate} \) anion to a heptadentate cationic terbium[III] complex at physiological pH. The aromatic carboxylate acts as a sensitising antenna capable of adequately populating the \(^5\text{D}_4\) \(\text{Tb}(\text{III})\) excited state of the ternary complex, while simultaneously displacing coordinated water molecules that quench the lanthanide emission, thereby signalling the presence of the anion. Hydration states determined using a Horrocks-based method, endorse bidentate carboxylate binding to form four-membered chelate rings, displacing inner-sphere water molecules. Consequently, sensing of aliphatic and aromatic dicarboxylates was further investigated using dinuclear terbium complexes. Dinuclear complexes encapsulated terbium[III] ions within a cyclen macrocycle bearing three pendent amide moieties, covalently linked via a \(p\)-xylyl spacer aimed at accommodating the binding requirements of the dicarboxylate anions. Each metal centre was shown to independently bind a \(\text{H}_{2}\text{N}-\text{dimethylamino} \)carboxylate anion in dinuclear ternary complexes with 2:1 stoichiometry. A 1:1 stoichiometry was observed for the luminescent ternary complex of terephthalic acid in which carboxylate moieties bind to separate metal centres forming four-membered chelate rings. A number of phthalate derivatives have been identified as metabolic and endocrine disruptors, capable of inducing hormone imbalance in humans with highly toxic effects. Recognition of aromatic dicarboxylates is therefore desirable in biological and aqueous media. Hexaazaamacrocyclic ligands consisting of amines linked by \(p\)-xylyl spacers and alkyl groups are reported to afford discriminatory recognition of phthalate isomers. Potentiometrically determined formation constants for phthalate ternary complexes with hexaaazaamacrocycles containing propylene groups, indicate recognition of the isophthalate complex is thermodynamically preferred. Inappropriate geometries of the \(\text{ortho}\) and \(\text{para}\) isomers inhibit optimal \(\text{N}\cdots\text{H} \cdots\text{O}\) and \(\text{C}\cdots\text{H} \cdots\text{O}\) hydrogen-bonding interactions with the terephthalate \((\text{para})\) complex exhibiting the weakest binding.

Europium[III] complexes of coordinatively saturated cyclen-based ligands, bearing four pendent side-arms, have been thoroughly scrutinised; their coordination polyhedra inevitably include a singular axially bound aqua ligand undergoing dissociative exchange with bulk water. The aqua ligand is, however, not readily substituted in aqueous media and anion sensing strategies infrequently consider octadentate europium[III] complexes. Unsaturated coordination has recently been reported for octadentate europium[III] complexes in which a brachial moiety is not bound to the metal centre. A pendent azaxanthonane group of a protein-bound octadentate europium[III] complex is reported to reside in the apolar binding cavity of the alpha-1-glycoprotein and is not coordinated to the metal centre. A change in ligand denticity may also be advanced for preferential citrate recognition by Eu(STP)(H2O), a cyclen-based octadentate europium[III] complex bearing four brachial hydroxypropyl moieties. Displacement of the weaker hydroxalkyl donors, in addition to the axially coordinated water molecule, facilitates...

Fig. 1 Ortep diagram of [Eu(CyD3MA)(CF3SO3)]2+. Thermal ellipsoids are shown at the 50% probability level.

Fig. 2 pH dependent emission spectra of Eu(III)-1,4,7-tris[N-methyl-carbamyl(methyl)-10-(2-hydroxy-cyclohexyl)-1,4,7,10-tetraazacyclododecane] (Eu(CyD3MA))3+ in buffered solution (KHP, MOPS, MES and TRIS). Insert: pH dependent emission modulation of the 5D0→7F1 transition.

Changes in hydration state (ESI† Table S3), with concomitant pH dependent modulation of Eu(III) emission (Fig. 2 and Fig. S5, ESI†), are likewise observed for a multicomponent buffer solution (KHP, MOPS, MES and TRIS) of [Eu(CyD3MA)]3+. The spectroscopic signature for the buffered [Eu(CyD3MA)]3+ solution is influenced by the formation of an ortho-phthalate ternary complex with unusually high values of q for an octadentate europium(III) complex below physiological pH (ESI† Table S3). Hydration states at lower pH support ligand heptadentancy upon formation of an outer-sphere [Eu(CyD3MA)(H2O)3]3+pht2− ternary complex, in which O4 equatorial binding of the hydroxycyclohexyl pendent is replaced by a second bound water molecule. pKq values of 4.7 ± 0.1 and 8.7 ± 0.1 are determined by non-linear regression analysis of luminescent data. Electronic absorption data (π→π* transition, 280 nm; pKd = 2.8 ± 0.2, pKd = 5.1 ± 0.1) confirms complete ortho-phthalate deprotonation in the ternary complex.
[Eu(CyD3MA)(H2O)2]3+ phthalate (ESI, Fig. S6 and S7). O–H · · · Ophthalate hydrogen-bonding interactions with inner-sphere water molecules and the uncoordinated hydroxyethyl pendant facilitate outer-sphere phthalate binding with subsequent energy transfer from the phthalate (ortho) antennae to the europium metal centre—sensitising europium(u) emission. Deprotonation of the coordinated water (pKa = 8.7) leads to weaker electrostatic attraction in the ternary [Eu(CyD3MA)(H2O)OH]2+ phthalate complex, evidenced by a decrease in intensity for all Eu(u) emission bands (the off-state). Phthalate displacement precedes hydroxycycloalkyl binding that results in the formation of the octadentate [Eu(CyD3MA)OH]25 complex, verified by the determined hydration state (q ~ 0.5) at elevated pH (ESI, Table S3). Modulation of europium(u) emission is not observed below physiological pH for a buffered [Eu(CyD3MA)]3+ solution that excludes KHP (ESI, Fig. S8). A single pKa (9.0 ± 0.1), determined from analysis of luminescence data (ESI, Fig. S9), compares favourably with that observed for [Eu(CyD3MA)(H2O)]3+ (pKa = 8.7) in aqueous solution, further confirming that modulation of lanthanide emission at lower pH is phthalate induced.

This study identifies mixed donor octadentate europium(u) complexes as potential alternatives for pH dependent recognition of anions with suitable spectroscopic signatures. Spectroscopically silent octadentate europium(u) complexes are generally considered inappropriate for recognition of chelating anions. Necessary pendant donor displacement for inner-sphere coordination, potentially compromises complex stability. This work demonstrates formation of ternary outer-sphere complexes of anions, capable of sensitising europium-based emission, provides an alternative recognition event associated with changes in hydration state and ligand denticity. In particular, ortho-phthalate recognition by a mixed donor octadentate europium(u) complex, [Eu(CyD3MA)]3+, is illustrated. The ortho-phthalate anion is shown to be an outer-sphere ligand and binding interactions result in hydration states (q ~ 2) more readily associated with heptadentate chelators. Pseudo-heptadentarity is achieved by incorporating a weaker binding brachial hydroxycycloalkyl group, susceptible to dissociation upon formation of an outer-sphere ternary complex. At higher pH values octadentarity is restored, as determined by hydration states characteristic of octadentate europium(u) complexes, upon ortho-phthalate displacement. The above mentioned responsive nature of mixed donor, octadentate europium(u) complexes merits further investigation that may potentially impact developments in anion and molecular recognition. Observations can further contribute towards the development of analogous responsive gadolinium(u) complexes suitable for applications in MRI imaging.
