Xylooligosaccharide increases bifidobacteria but not lactobacilli in human gut microbiota

Xylooligosaccharide increases bifidobacteria but not lactobacilli in human gut microbiota

Cite this: *Food Funct.*, 2014, 5, 436Sydney M. Finegold,^{*abcd} Zhaoping Li,^{bde} Paula H. Summanen,^b Julia Downes,^b Gail Thames,^{de} Karen Corbett,^b Scot Dowd,^f Michael Krak^{de} and David Heber^{de}

This study was conducted to determine the tolerance and effects of the prebiotic xylooligosaccharide (XOS) on the composition of human colonic microbiota, pH and short chain fatty acids (SCFA) in order to determine whether significant changes in the microbiota would be achievable without side effects. Healthy adult subjects ($n = 32$) were recruited in a double-blind, randomized, placebo-controlled study. Subjects received 1.4 g XOS, 2.8 g XOS or placebo in daily doses. The study consisted of a 2 week run-in, an 8 week intervention, and a 2 week washout phase. Stool samples were collected at baseline, after 4 and 8 weeks of intervention and 2 weeks after cessation of intervention. Samples were subjected to culture, pyrosequencing of community DNA, pH and SCFA analyses. Tolerance was evaluated by daily symptom charts. XOS was tolerated without significant gastrointestinal side effects. *Bifidobacterium* counts increased in both XOS groups compared to the placebo subjects, the 2.8 g per day group showed significantly greater increases than the 1.4 g per day group. Total anaerobic counts and *Bacteroides fragilis* group counts were significantly higher in the 2.8 g per day XOS group. There were no significant differences in the counts of *Lactobacillus*, *Enterobacteriaceae* and *Clostridium* between the three groups. XOS intervention had no significant effect on stool pH, SCFA or lactic acid. Pyrosequencing showed no notable shifts in bacterial diversity. XOS supplementation may be beneficial to gastrointestinal microbiota and 2.8 g per day may be more effective than 1.4 g per day. The low dose required and lack of gastrointestinal side effects makes the use of XOS as a food supplement feasible.

Introduction

The gastrointestinal microbiota is important in human gastrointestinal and general health. Adding a prebiotic to the diet can increase beneficial gut bacteria, thus generating benefits to overall health. These benefits include improved digestion and gut function, potential protection from colon cancer,¹ reduced symptoms of irritable bowel syndrome,² immune regulation,³ and possible management of obesity.⁴ Prebiotics are not absorbed or digested by humans, but can have a significant effect on the human gut microbiota which digest them, favoring proliferation of some species over others. Studies of the gut

microbiota have shown that the *Firmicutes/Bacteroidetes* (F/B) ratio differed in obese and lean human subjects, mainly due to a reduced *Bacteroidetes* proportion in obese subjects, suggesting that modulating the abundance of specific bacterial communities might be beneficial in the treatment of obesity.^{5,6} Similar changes in the F/B ratio have been demonstrated in mice with varying genetic susceptibility to weight gain on a high fat/high sucrose diet.⁷ Recent human studies have linked increased *Lactobacillus* counts^{8,9} and decreased *Bifidobacterium* counts to obesity.^{10–12} *Lactobacillus* may promote obesity based on their impact on food conversion and weight gain, which has been demonstrated in farm animals.¹³

When prebiotics were compared, *Bifidobacterium* spp. favored xylooligosaccharides (XOS), raffinose and fructooligosaccharides (FOS) over hexoses (such as glucose) in *in vitro* growth experiments.¹⁴ Rycroft *et al.* also evaluated the fermentative properties of some prebiotics *in vitro* and found that XOS and lactulose produced the highest increases in bifidobacteria, while FOS led to the promotion of the growth of lactobacilli.¹⁵ Human and animal studies demonstrate that XOS is a efficacious prebiotic that can change the microbiota at a level as low as 1.4 g per day in adults,¹⁶ which is much lower than levels required by FOS (≥ 10 g per day)¹⁷ or galactooligosaccharides

(GOS, ≥ 10 g per day).¹⁸ At these lower doses, we reasoned that gastrointestinal side effects with XOS might be less common.

The xylooligosaccharides are oligomers of unconventional sugars, formed by xylose units, which are non-caloric and not digestible by humans. They are found in fruits, vegetables, milk and honey. The production of XOS for human consumption occurs through the industrial production of lignocellulosic materials (LCMs), obtained from a variety of forest residues (eucalyptus wood) or agro-industries (corn cob, almond, olive, rice hulls, oats, barley).^{19–21} The aim of the present study was to determine the effects of XOS on the composition of human colonic microbiota, pH, fecal short chain fatty acids (SCFA) and lactic acid, and to determine the tolerance of XOS by healthy adult subjects.

Materials and methods

Subjects

A double blind, randomized, placebo-controlled study design was carried out with 32 subjects who were recruited based on inclusion and exclusion criteria. The study population consisted of 21 healthy adult women ranging from 21 to 49 years of age (mean age 33.6 years, mean BMI 24.1) and 11 healthy adult men ranging from 23 to 34 years of age (mean age 30.1 years, mean BMI 25.6). Subjects with a history of cigarette smoking in the past 5 years, history of bleeding disorders, inflammatory bowel diseases (Crohn's/ulcerative colitis), irritable bowel syndrome, gastrointestinal surgery within the past 2 years, diabetes, cardiovascular disease, hypertension, regular intake of nonsteroidal anti-inflammatory drugs (NSAIDs), steroids, or other anti-inflammatory medications, use of antibiotics (other than topical) in the past 2 months and current use of dietary supplements, including probiotics and prebiotics were excluded.

Study protocol

Subjects were randomly assigned to take daily capsule supplements containing either 1.4 g XOS, 2.8 g XOS, or placebo. The XOS supplements and placebo were provided by Life Bridge, International (Riverside, CA). XOS was manufactured by Shandong Longlive Bio-Technology Co., Ltd., China. Each 1.4 g XOS supplement capsule contained white or off-white crystalline substance (175 mg XOS) and the 2.8 g XOS supplement capsule contained white or off-white crystalline substance (350 mg XOS). The placebo capsules were identical in appearance to the XOS capsules and contained maltodextrin. The supplements were stored (room temperature) at the UCLA Center for Human Nutrition. The study consisted of three phases: a 2 week run-in phase, an 8 week intervention phase, and a 2 week washout phase. During the 2 week run-in phase all subjects were instructed to maintain their usual diet but to restrict consumption of products containing high levels of XOS or other oligosaccharides (soybean, onion, asparagus, wheat, rye, triticale, and chicory) and fermented dairy products containing viable bifidobacteria or lactobacilli. All subjects were instructed to continue these dietary guidelines throughout the 8 week intervention and 2 week washout phase. A 24 hour dietary recall

was performed at baseline (*i.e.*, at the end of the 2 week run-in phase at week 0), week 4, week 8, and week 10 (*i.e.*, at the end of the 2 week washout phase) for calculation of total energy intake and the amount of carbohydrates, fiber, fat and protein. This dietary inquiry was also used to assess dietary compliance of subjects. Tolerance was evaluated by using a daily chart where the symptoms (excess flatus, borborygmi, bloating, abdominal pain) were graded from 0 (no symptoms) to 3 (severe symptoms). Frequency and consistency of stools were also noted with diarrhea defined as one or more liquid stools or more than 3 stools per day.

Stool collection and processing

A total of four stools were collected from each subject: at baseline, after 4 weeks, and 8 weeks of intervention with XOS or placebo, and at 2 weeks after cessation of XOS or placebo intervention (week 10). Each time the entire stool specimen was obtained. The specimen was placed in a large, zip-lock freezer bag and all air was pushed out of the bag as the zip lock was closed. The specimen was delivered on ice to the UCLA Center for Human Nutrition within 24 hours of collection where it was immediately stored at -20°C . At the VA Medical Center laboratory, the specimens were weighed and placed into an anaerobic chamber for processing. Approximately 1 g of the stool was weighed and dried in a vacuum drying oven (15 in Hg) at 80°C for 48 hours, then weighed again to establish the moisture content so that all counts could be corrected to dry weight. The stool samples were diluted in pre-reduced phosphate buffered saline (PBS) in appropriate amounts to allow mixing and then homogenized in a Waring blender.

Pyrosequencing

DNA was extracted from 200 μg of stool homogenate using the commercial extraction system QIAamp® Stool DNA Extraction Kit (Qiagen, Valencia, CA), and sent to Dr Dowd at MR DNA Molecular Research laboratory for pyrosequencing. The quality of the DNA samples was confirmed using a Bio-Rad Experion system (Bio-Rad Laboratories, CA, USA). Bacterial tag-encoded FLX-titanium amplicon pyrosequencing (bTE-FAP) was performed as described previously.^{22–24} This approach utilizes GS FLX Titanium series reagents and procedures (454 Life Sciences, CT, USA) and a one-step PCR, mixture of Hot Start and Hot Start high fidelity taq polymerases, and amplicons originating from the 27F region numbered in relation to *E. coli* rRNA. Statistical analysis was performed using a variety of computer packages including XLstat, NCSS 2007, "R" and NCSS 2010. Alpha diversity analysis was conducted as described previously.^{22–24} Beta diversity analysis was performed by creating individual phylogenetic trees, without regard for taxonomy, for each sample then statistically evaluating each tree among each sample. A principal coordinate analysis was then performed to allow for visualization of 10 separate jackknife iterative comparisons. The multidimensional space was then described within the 3 primary vectors.

Stool pH and SCFA

1 g of the stool was used to make a 1 : 5 dilution in sterile distilled water. The pH was measured using a pH meter (Corning). Gas liquid chromatography (GLC) for short-chain volatile and non-volatile fatty acid analyses was then performed as described previously.^{25–27} Total SCFA were expressed as micromoles per gram of dry weight stool.

Stool microbiology

Specimens were cultured for total bacterial flora and total anaerobic and aerobic counts were recorded. Selective and differential media were used as indicated to grow and enumerate *Enterobacteriaceae*, *Bacteroides fragilis* group, *Clostridium*, *Bifidobacterium*, and *Lactobacillus*. Aliquots of the homogenized specimens were diluted in pre-reduced PBS appropriately and plated (100 µl per plate) onto Brucella blood agar (BD BBL, Sparks, MD) for total anaerobic count, Trypticase Soy blood agar (TSA, BD BBL) for total aerobic count, Bacteroides-bile-esculin agar (BBE; BD BBL) to enumerate *Bacteroides fragilis* group and MacConkey agar plates (BD BBL) to enumerate *Enterobacteriaceae*. The *Bifidobacterium* medium consisted of 42.5 g Columbia agar base (BD BBL), 5 g glucose, 0.4 g cysteine, 0.01 g riboflavin, and 0.8 ml propionic acid in 1 liter dH₂O. The *Lactobacillus* medium consisted of 84 g LBS agar (BD BBL) and 1.32 ml glacial acetic acid in 1 liter dH₂O. For the selective isolation of *Clostridium*, diluted aliquots of the stool specimens were incubated in 50% ethanol for 30 min, and subsequently plated onto Brucella agar plates. Brucella agar plates for total anaerobic count and the *Bifidobacterium* medium and *Lactobacillus* medium plates were incubated under anaerobic conditions at 37 °C for 7 days; BBE and Brucella plates for *Clostridium* enrichment were incubated under anaerobic conditions at 37 °C for 5 days. Anaerobic conditions consisted of a gas mixture of 5% CO₂, 5% H₂, and 90% N₂; the residual oxygen was removed by palladium catalysts. TSA blood agar plates were incubated under 10% CO₂ for 72 hours and MacConkey agar plates aerobically at 37 °C for 24 hours. Characteristic colony types on various selective media were counted and the counts were adjusted to dry weight of stool. The identity of all colony types on the *Lactobacillus* and *Bifidobacterium* selective media were confirmed to the species level by 16S rRNA gene sequencing. Details of the culture techniques are described in the Wadsworth-KTL Anaerobic Bacteriology Manual.²⁵

16S rRNA gene sequencing

Genomic DNA was extracted and purified from bacterial cells using a QIAamp DNA Mini Kit (Qiagen). The 16S rRNA gene fragments were amplified using universal primers 8UA and 907B as previously described.²⁸ The purified PCR products were sequenced directly with a Biotech Diagnostic Big Dye sequencing kit (Biotech Diagnostics, CA) on an ABI 3130 *Avant* sequencer (Applied Biosystems, Foster City, CA). The sequencing data was analyzed by comparison of the consensus sequences with GenBank sequences by using Ribosomal Database Project (RDP-II) (Michigan State University, East Lansing),²⁹ and Basic Local

Alignment Search Tool (BLAST).³⁰ Analysis of the isolates was performed by comparing with the sequences of the type strains retrieved from GenBank by using the program Clustal W.³¹

Ethics

The study was carried out in accordance with the guidelines of the Office for Protection of Research Subjects of the University of California, Los Angeles and the Institutional Review Board of the VA Greater LA Health Center. All subjects provided written informed consent before the study began.

Statistics

The treatment effect for all the variables was determined by comparing mean changes from baseline across dose groups and within groups across time using a (time × dose) repeated measure analysis of variance (ANOVA) model. For pyrosequencing analyses, Kruskal–Wallis with multiple pairwise comparisons using the Steel–Dwass–Critchlow–Fligner procedure and two-tailed test was utilized to evaluate the differences among each study group. Repeated measures ANOVA were also performed and for variables which did not follow normal distribution (lots of zero's) the medians were reported and compared using Kruskal–Wallis (Wilcoxon Rank Sum) test. Significance reported for any analysis was defined as $p \leq 0.05$.

Results

Subjects

A total of 32 subjects were enrolled into the study. One subject from the placebo group and one from the low dose group dropped out of the study for non specific gastrointestinal complaints. One placebo group subject, two high dose group subjects, and two low dose group subjects were excluded from the analyses because of compromised specimen quality. Analysis was performed on 100 samples consisting of 7 high dose group, 9 low dose group, and 9 placebo group subjects.

Stool microbiology

The 16S rRNA gene sequencing revealed that *Bifidobacterium longum* was the most commonly isolated *Bifidobacterium* sp. (found in 81% of the specimens) followed by *Bifidobacterium pseudocatenulatum/catenulatum* (45%), *Bifidobacterium bifidum* (29%) and *Bifidobacterium adolescentis* (28%). Various *Lactobacillus* species were identified, most commonly *Lactobacillus casei/paracasei* (29%), *Lactobacillus gasseri* (22%), and *Lactobacillus acidophilus* (15%) (Table 1). The mean counts (cfu g⁻¹ dry weight stool), standard deviations and p -values (for comparison to baseline) of the different groups of bacteria are presented in Table 2. Table 3 presents the p -values of the mean change in counts in comparison to the baseline values comparing the three study groups against each other at weeks 4, 8 and 10. The *Bifidobacterium* counts of the subjects after high dose (2.8 g per day) XOS intervention was significantly higher than the values at the baseline at 4, 8, and 10 weeks (Table 2). Similarly, the

counts between the three study groups evaluated, whereas the *Enterobacteriaceae* count was significantly lower at week 10 in the placebo group (Tables 2 and 3).

Microbiome

A total of 997 322 sequences were derived from the 100 samples in the study. One sample was excluded (baseline) due to low sequence counts. After stringent quality sequence curation and rarefaction a total of 460 727 sequences classified within the bacterial kingdom were utilized for final microbiota analyses with an average of 4607 sequences per sample. The number of operational taxonomic units (OTU) at the species level was evaluated to define alpha diversity among the different groups. Based upon temporal and dosage compound variables there were no significant differences in the observed OTUs (Table 4). Similarly the Shannon index (Table 4) did not indicate significant differences among the groups. This indicates there were no notable shifts in the diversity of the bacterial communities due to the treatments. Similarly, in the current analysis we did not see appreciable clustering of the data based upon ongoing treatments compared to subjects not receiving treatment (Fig. 1). When adding the high and low after washout there was

still no notable clustering of samples. A dendrogram created utilizing Wards clustering and Manhattan distances to illustrate potential shifts at the genus taxonomic level showed that the samples had no notable separation related to the treatment and that the samples from individual subjects tended to cluster together indicating that the microbiome of each individual tended to be more similar to the original microbiome regardless of treatment (data not shown). Finally, repeated measures ANOVA analyses of possible individual genera that were altered related to the treatment revealed that the proportion of *Faecalibacterium* of the subjects after high dose XOS intervention was significantly higher than the baseline at 4 weeks ($p = 0.019$) (Table 5). Non-parametric *p*-value obtained using Kruskal–Wallis (Wilcoxon Rank Sum) test showed significant increase in the proportion of *Akkermansia* from the baseline in the high XOS group compared to the placebo group subjects at 8 weeks ($p = 0.041$), and in the high XOS group compared to the low XOS group subjects at 10 weeks ($p = 0.055$).

Stool pH and SCFA

At baseline, the mean stool pH was 6.9. No significant, intervention-related differences in stool pH, mass, or total SCFA were

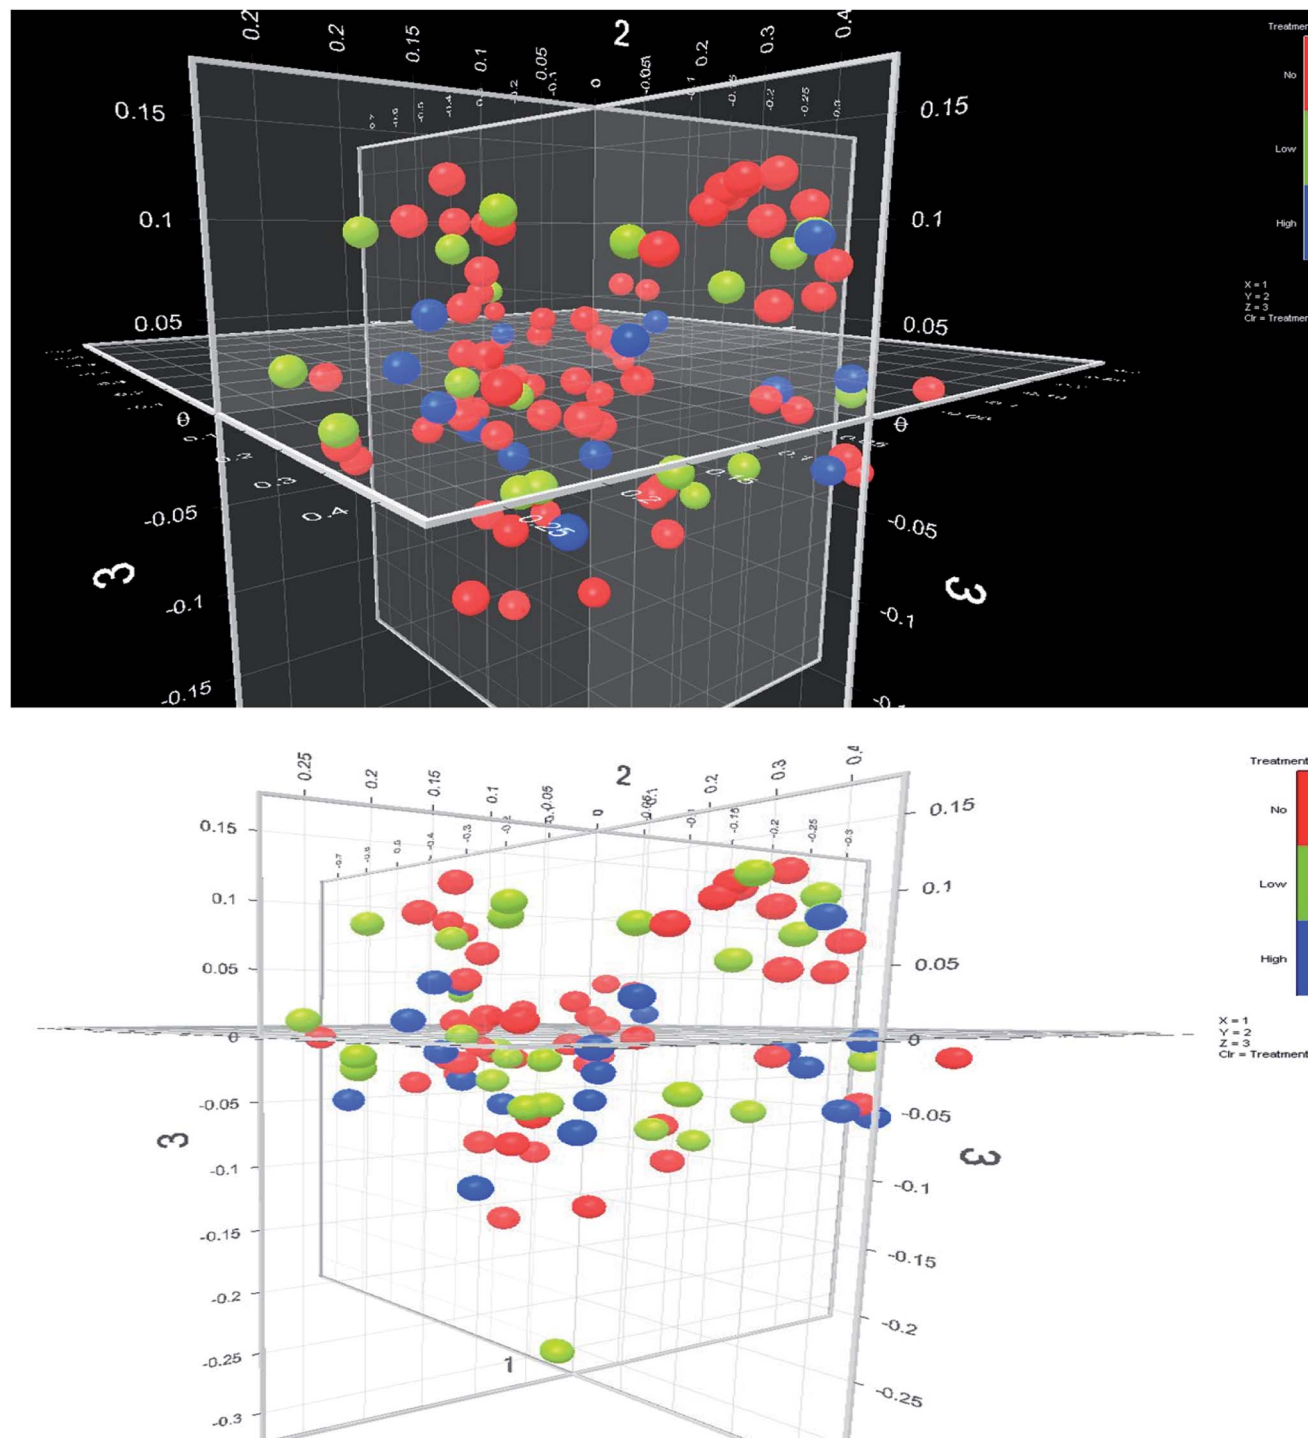

Fig. 1 Beta diversity analysis. The no designations include all subjects prior to receiving supplement, subjects receiving placebo, and subjects after washout period. The high and low indicate those subjects receiving the indicated dosage at those periods when they were actively receiving treatment.

observed (Table 6). Similarly, no significant, intervention-related differences in the individual SCFA were observed. Low levels of lactic acid ($\leq 50 \mu\text{M}$) were detected in only three of 100 samples.

Tolerance

The gastrointestinal symptom results are shown in Table 7. No subjects had severe symptoms during the study period and no

subjects had diarrhea by definition of liquid stool or more than 3 stools a day.

Discussion

The potential for prebiotics to be effective in the treatment of metabolic disorders and obesity is an area of potentially great significance. Studies have shown a decreased number of

Bifidobacterium in the stools of obese subjects,^{10–12} and that administration of a *Bifidobacterium breve* to mice with high-fat diet-induced obesity led to a significant weight decrease.³² In the present study, both high and low dose XOS groups showed significantly higher counts of *Bifidobacterium* species than the placebo group, with the higher dose group showing significantly greater increases than the lower dose group. The *Bifidobacterium* count increased 21% from the baseline at 4 weeks and 17% from the baseline at 8 weeks in the high dose group. In addition to increasing the number of *Bifidobacterium*, this study also found a significant increase in the *B. fragilis* group (a member of the *Bacteroidetes*) for the high dose XOS group, and that XOS supplementation did not increase *Lactobacillus* (a member of the *Firmicutes*). Recent human studies have suggested that obesity-associated gut microbiota has increased numbers of *Lactobacillus*^{8,9} and an increased *Firmicutes/Bacteroidetes* ratio.^{5,6} Our findings suggest that XOS supplementation may be useful in the management of obesity. The increase in the counts of the “total anaerobes” in the high dose group reflects the increased counts in the *Bifidobacterium* and *B. fragilis* group,

both of which are anaerobic. Some *Bifidobacterium* species may grow aerobically as well, which may be reflected in the modest increase of the aerobic counts in the high dose XOS group.

To our knowledge, this is the first study examining the effect of prebiotics on the human intestinal bifidobacteria and lactobacilli where the identity of these organisms was confirmed by 16S rRNA sequencing. Only confirmed colonies were utilized in the final counts, thereby yielding more accurate counts than just relying on typical colony morphologies on selective media. While selective media are an invaluable tool in culturing stool samples, other organisms besides bifidobacteria and lactobacilli do grow on these media and not all target colonies are necessarily “typical”. By verifying the species identification, we also obtained valuable information on the *Bifidobacterium* and *Lactobacillus* species distribution in normal human intestinal flora. Turrone *et al.* studied the distribution of bifidobacteria in normal human gut by selective culture combined with 16S rRNA gene and 16S–23S internally transcribed spacer [ITS] sequencing, and found a similar species distribution to that found in this study.³³ *L. casei/paracasei* was the most commonly isolated *Lactobacillus* species in our study, similar to another recent culture-based study,³⁴ whereas a non-culture based study on a Japanese population found *L. fermentum* as the most predominant *Lactobacillus* species.³⁵ In our study, the mean count of *Bifidobacterium* at baseline was 8.8×10^8 cfu g⁻¹ and *Lactobacillus* 2.4×10^6 cfu g⁻¹ dry weight stool. Similar numbers have been reported in previous studies^{33–35} indicating that bifidobacteria outnumber lactobacilli in the human gut.

The pyrosequencing results in this study indicate that the XOS supplementation did not result in significant shifts in the diversity of the bacterial communities. The 16S rRNA gene-based pyrosequencing approach has been shown to underestimate *Bifidobacterium*,^{24,36} which might account for the difference between the pyrosequencing and the culture results in this study. At genus level pyrosequencing analysis, the genera that were significantly increased were *Faecalibacterium* sp. and *Akkermansia* sp. in subjects on high dose XOS supplementation. *Faecalibacterium* sp. is a butyrate-producer with known

anti-inflammatory effects in the gut, and low fecal concentrations of *Faecalibacterium* sp. have been reported in IBD and Crohn's disease.³⁷ *Akkermansia* is a mucin-degrading gut bacterium associated with gut health.³⁸ It has recently been reported that the counts of *Akkermansia* decreased in obese and type 2 diabetic mice, and that a prebiotic (oligofructose) feeding normalized the *Akkermansia* numbers correlating with improved metabolic profile.³⁹ Our results suggest that XOS may be a suitable prebiotic for the promotion of *Akkermansia* in the human gut.

Na and Kim investigated the effects of 1.4 g per day and 2.8 g per day doses of XOS on stool bifidobacteria proliferation, lactic acid concentration and lipid metabolism in healthy Korean women, and as in this study, they found that the number of *Bifidobacterium* increased significantly in both XOS groups.¹⁶ They also found that serum triglyceride, cholesterol and glucose concentrations were significantly decreased in the 2.8 g per day intake group; while there were significant increases in concentrations of stool cholesterol in both groups, and stool triglycerides in the 2.8 g per day group. In their study the stool lactic acid concentration was significantly increased and the fecal pH significantly decreased in the 2.8 g per day intake group.¹⁶ In the present study, however, the XOS supplementation had no significant effect on stool pH or SCFA, with low levels of lactic acid ($\leq 50 \mu\text{M}$) detected in only three samples. Other studies have similarly shown no significant increases in fecal pH and SCFA in subjects on prebiotic supplementation; this is probably due to the metabolism of SCFA by the host.^{40,41} Another study assessing the effects of a 4 g per day dose of XOS on the intestinal microbiota, gastrointestinal function and nutritional parameters in elderly patients over a 21 day period concluded that XOS supplementation promoted intestinal health and showed no adverse effects on the elderly study population.⁴²

A requirement for an effective prebiotic would be the absence of gastrointestinal side effects. In the current study, both 1.4 g per day and 2.8 g per day doses of XOS were tolerated well by normal healthy adults without any gastrointestinal side effects above those observed in the placebo group. The dose of FOS required to significantly increase the *Bifidobacterium* counts in the human gut is in the range of 10 to 20 grams.¹⁷ In a threshold study evaluating symptomatic response to varying levels of FOS ingested regularly, excessive flatus and borborygmi were recorded by about 10% of volunteers at 10 g per day of FOS and excessive flatus, borborygmi and bloating by about 20–30% of volunteers at 20 g per day.⁴³ In another study in which 10 volunteers ingested 15 g per day FOS for 12 days, gaseous symptoms such as abdominal cramps, excess flatus and bloating were significantly more severe in subjects ingesting the FOS than in sucrose-fed control subjects.⁴⁴ A dose-effect relationship was previously found using another bifidogenic substrate, GOS, but the minimal dose that significantly increased fecal bifidobacteria counts was 10 g per day, and the maximal well-tolerated dose was 15 g per day.¹⁸ In the present study, XOS increased bifidobacteria count in a dose-response manner at much lower doses than FOS or GOS, without any significant increase of gastrointestinal symptoms compared to subjects on placebo. The lower effective dose of XOS by comparison to FOS and

GOS, makes XOS incorporation into food products or capsules more feasible.

Based on the findings of the current study, XOS dietary supplementation may be beneficial to gastrointestinal microbiota and a dose of 2.8 g per day maybe more effective at producing these outcomes than a lower dose of 1.4 g per day. This study demonstrated that XOS increases the counts of *Bifidobacterium* without increasing the counts of *Lactobacillus* in healthy adults. Further clinical studies will determine whether XOS may have utility in the prevention and treatment of metabolic disorders including obesity.
