Recently, a series of transition metals have been extensively explored for the construction of aryl C–F bonds. The introduction of inexpensive copper reagents instead of Pd and Ag complexes would be promising methods for scalable production of aryl fluorides without concomitant hazardous wastes. This highlight mainly focused on recent advances in copper-mediated/-catalyzed fluorination reactions to construct aryl fluorides.

Widespread application of aryl fluorides in pharmaceuticals, agrichemicals, medical diagnosis (positron emission tomography, PET) and materials science has provoked general interest in the development of methodologies for the construction of aryl C–F bonds.¹ Quite recently, the prominence of transition-mediated/-catalyzed fluorination protocols has received much attention. In spite of the tremendous efforts which have been dedicated to the practical procedures, the successful examples were limited to palladium and silver catalytic systems.² The

newly emerged fluorination strategy using copper complexes provides promising alternatives to lower the costs towards potential large scale production. This paper highlights recent progress in this issue.

In 2002, Buchwald and co-workers illustrated the first copper-catalyzed halide exchange reactions to synthesize aryl iodides from the corresponding aryl bromides using catalytic amounts of CuI/ligands and NaI as an iodide source.³ However, a comparable mode towards aryl fluorides from aryl bromides and iodides is actually a more challenging issue. In 2006, Grushin reported that stoichiometric amounts of CuF₂ can be used to achieve fluorination of phenyl iodide in strong polar solvent (HMPA).⁴ However, relatively low yield and

Xin Mu

Xin Mu received his B.S. in Chemistry from Zhejiang University in 2008. He then attended the Shanghai Institute of Organic Chemistry, CAS, for his Ph.D. program in the laboratory of Prof. Guosheng Liu's group, where his Ph.D. work focused on transition metal-catalyzed tri-fluoromethylation and fluorination reactions. After earning his Ph.D. in 2013, he is now carrying out postdoctoral research with Prof. Greg C. Fu at the California Institute of Technology.

Guosheng Liu

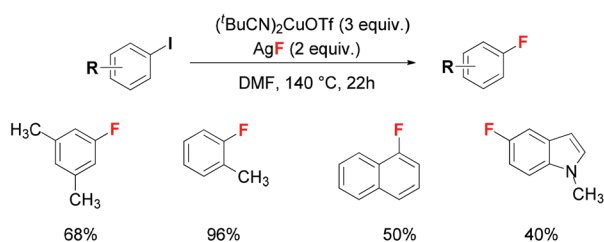

Guosheng Liu studied chemistry at Nanjing University of Science and Technology (1995) and obtained his M.S. at the Dalian Institute of Physical Chemistry, Chinese Academy of Science (CAS), China (1999), with Prof. Zhuo Zheng. He then moved to the group of Prof. Xiyan Lu at the Shanghai Institute of Organic Chemistry, CAS, where he received his Ph.D. in 2002. From 2003 to 2007 he conducted postdoctoral research at Lehigh University with Prof. Li Jia and at the University of Wisconsin—Madison with Prof. Shannon S. Stahl. In 2007 he began his independent career at the Shanghai Institute of Organic Chemistry, CAS. His current research interests focus on the development of novel synthetic methodologies and degradable polymer synthesis.

inseparable dehalogenation byproducts limited its further application. Later on, in 2011, Ribas and co-workers reported well-defined aryl-Cu(III)X (X = Cl, Br, I) complexes to depict the viable involvement of Cu(III) intermediates in these halide exchange processes including the rare aryl C–F bond formation process.⁵ A sequence involving X-type ligand exchange with the fluoride anion and reductive elimination from the aryl-Cu(III)–F centre was proposed for the scenario (Scheme 1a). Computational studies revealed that aryl C–F reductive elimination is a much more favored process than aryl C–Cl reductive elimination. In addition, the halide exchange on the Cu(III) centre was significantly influenced by the solubility of inorganic fluorides. Finally, the authors also demonstrated the first copper-catalyzed fluorination of aryl chloride within the rigid structure framework (Scheme 1b). Wang and co-workers also independently reported a similar fluorination pattern with a rigid tridentate-nitrogen containing ligand (Scheme 1c).⁶ These two cases have interpreted the operative aryl C–F bond formation from Cu(III) complexes; however, to advance this protocol towards preparative methods for the aryl fluorides remains a challenging task.

Recently, Hartwig provided a procedure for copper-mediated fluorination of diverse functionalized aryl iodides using AgF as a fluorine source (Scheme 2).⁷ For less reactive

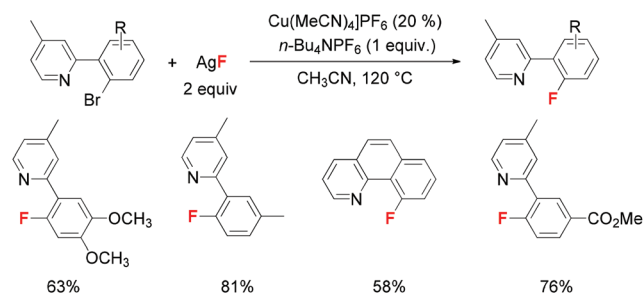

Scheme 2 Copper-mediated fluorination of aryl iodides.

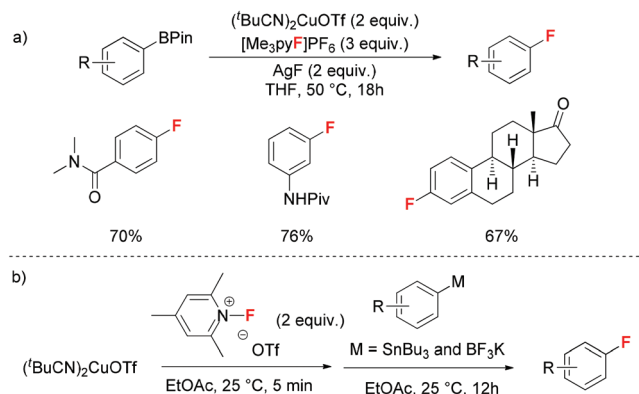

aryl bromides, low conversion and yield was obtained. The author emphasized that an excess amount of copper reagents than AgF is essential for this process due to the side effect of AgF which acted as an oxidant to consume the reactive Cu(I) reagent. Dehalogenation byproducts were also observed during the fluorination reaction. Deuterium-labelling experiments indicated that adventitious water in the reaction system was the hydride source. Furthermore, mechanistic illustration excluded the single-electron-transfer (SET) pathway and an Ar-Cu(III)–F intermediate was proposed for this transformation.

Quite recently, Liu and co-workers reported a novel copper-catalyzed fluorination of allylic bromides and chlorides.⁸ The success of this halide exchange process relied on pre-installed weak coordinating groups such as carbonyl, ester and phthalimide to facilitate coordination with the copper catalyst, which is helpful to promote the subsequent oxidative addition step. Inspired by this important finding, Liu and co-workers developed a copper-catalyzed fluorination of aryl bromides in the presence of *ortho*-pyridine coordinating groups (Scheme 3).⁹ Extensive mechanistic rationale suggested that the pyridyl group will promote oxidative addition toward the aryl C–Br bond and alleviate the oxidation of the copper catalyst by AgF, and this conclusion was further supported by further XANES/EXAFS experiments. In addition, the electron-rich pyridine group significantly promoted the reaction rate than its electron-deficient counterparts which again addressed the vital role of pyridyl directing groups. For the aryl bromide moiety, substrates with electron-rich substituents also exhibited a slight acceleration effect which is consistent with a Cu(I/III) mechanism. Based on the above observations, the authors suggested that this reaction involves a rate-limiting oxidative addition step toward the aryl C–Br bond.

As alternative aryl sources, readily available aryl boron reagents have been successfully applied in copper-mediated fluorination reactions. Recently, Hartwig demonstrated a general procedure to prepare aryl fluorides using electrophilic fluorinating reagents as the fluorine source (Scheme 4a).¹⁰ Arylboronate esters provided better yields than other boronic acid derivatives. Inorganic fluoride salts were beneficial to promote the transmetalation step without affecting the base-sensitive fluoro-pyridinium reagents. Both NMR experiments and DFT calculations illustrated two eminent Cu(III)–F structures in THF solutions. Initial oxidation of Cu(I) reagents by

Scheme 4 Copper-mediated fluorination of aryl metal reagents with electrophilic fluorinating reagents.

fluoro-pyridinium reagents rendered Cu(III)-F species, and the following transmetalation with aryl boron esters and rate-determining reductive elimination produced the aryl fluorides. Meanwhile, Sanford and co-workers described a two-step synthesis of aryl fluorides starting from aryl stannanes and aryl trifluoroborates (Scheme 4b).¹¹ Sequential addition of electrophilic fluorinating reagents and aryl reagents provided much higher yields than the one-pot procedure.

A more desirable method employing inorganic fluoride salts instead of organic electrophilic fluorinating reagents was developed quite recently by Sanford and co-workers (Scheme 5).¹² Aryl trifluoroborates could be converted to the corresponding aryl fluorides in the presence of four equivalents of KF and Cu(OTf)_2 reagents. The authors emphasized the key oxidation step in which additional Cu(OTf)_2 would oxidize the ArCu(II)-F species produced from transmetalation to form the ArCu(III)-F intermediate.

Compared to the above mentioned fluorination of aryl halides and aryl boronates, direct fluorination of the aryl C-H bond would be a more straightforward strategy towards the aryl fluorides. A set of examples have been reported by Daugulis and co-workers using 8-aminoquinoline auxiliary to facilitate copper-catalyzed aryl C-H bond sulfenylation and amination reactions.¹³ The same directing group was applied in copper catalyzed aryl C-H bond fluorination reactions with AgF as a fluorine source (Scheme 6).¹⁴ Two sets of optimal reaction conditions with or without pyridine additive were developed to achieve mono-fluorination or di-fluorination pro-

ducts. This is the only case for copper-catalyzed direct C-H bond fluorination reactions. However, the detailed mechanism is not clear at the moment.

Conclusion and perspective

The copper-mediated/-catalyzed fluorination of aryl reagents has recently received much attention. Although some progress has been achieved, preliminary mechanistic interpretations have been provided to address the formation of aryl C-F bonds. However, this research field is still in its infancy, and the detailed mechanism remains unclear at this stage. In the future, a catalytic version of these reactions would be anticipated based on further detailed analysis of reaction intermediates and elaborate design of new ligands and copper catalysts in order to make this toolbox more applicable.
