Multiple photosynthetic reaction centres of porphyrinic polypeptide–Li⁺@C₆₀ supramolecular complexes†

Kei Ohkubo,^{*ab} Tetsuya Hasegawa,^a Régis Rein,^{cd} Nathalie Solladié^{*cd} and Shunichi Fukuzumi^{*abe}

Multiple photosynthetic reaction centres have been successfully constructed using strong supramolecular complexes of free base porphyrin polypeptides with lithium ion-encapsulated C₆₀ (Li⁺@C₆₀) as compared with those of C₆₀. Efficient energy migration and electron transfer occur in the supramolecular complexes.

Extensive effort has so far been devoted to mimicking light harvesting and charge separation processes in natural photosynthesis.^{1–10} Multiporphyrin arrays have been employed as light-harvesting units.^{11–17} Light-harvesting and charge-separation units have been combined by coordination bonds between metalloporphyrins and electron acceptor moieties bearing Lewis base ligands.^{17–22} Thus, metal centres were required for the construction of supramolecular complexes between porphyrins acting as light harvesting units and electron acceptors containing Lewis base ligands for coordination to the metal centres.^{17–22} As such there have been only a few reports on supramolecular complexes of free base porphyrin arrays and electron acceptors without Lewis base ligands, in which the binding is rather weak.²³ We report herein the construction of supramolecular complexes of free base porphyrin polypeptides (P(H₂P)_{*n*}; *n* = 4 and 8) with lithium ion-encapsulated C₆₀ (Li⁺@C₆₀)^{24,25} (Fig. 1), in which binding is much stronger than the case of C₆₀ in benzonitrile (PhCN). The photodynamics were studied by femtosecond and nanosecond laser-induced transient absorption and fluorescence lifetime measurements.

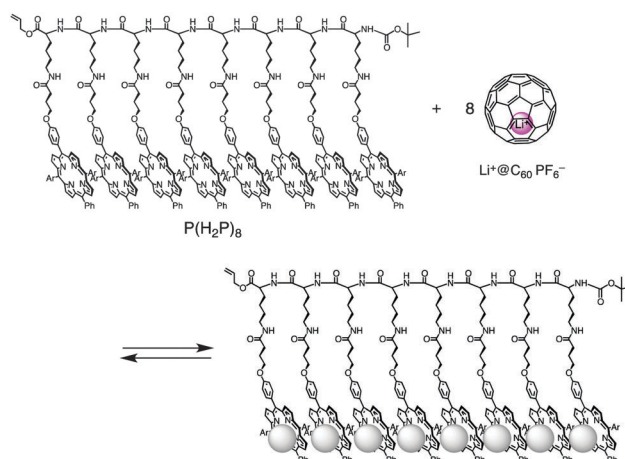

Fig. 1 Supramolecular formation of peptide porphyrin oligomers with Li⁺@C₆₀. Ar = 3,5-di-*tert*-butylphenyl.

Free base porphyrin polypeptide (P(H₂P)_{*n*}) were synthesised and characterised as reported previously.^{18,26} Upon mixing a PhCN solution of Li⁺@C₆₀ with that of P(H₂P)₈, the intensity of the Soret band decreased with an increasing concentration of Li⁺@C₆₀ (Fig. 2a). A Soret band was slightly red-shifted from 425 to 427 nm by the addition of Li⁺@C₆₀ to the solution. From the net absorption change at 425 nm in which the absorption due to Li⁺@C₆₀ was subtracted, a linear Benesi–Hildebrand plot²⁷ was obtained as shown in Fig. 2b, indicating that each porphyrin unit of P(H₂P)₈ forms a 1 : 1 supramolecular charge-transfer complex with Li⁺@C₆₀ independently with approximately the same binding constant of the unit of M⁻¹. The binding constant at 298 K was determined from the intercept and the slope in Fig. 2b to be 2.1 × 10⁴ M⁻¹, which is significantly larger than that of C₆₀ (5.3 × 10³ M⁻¹).^{28,29} The stronger binding of Li⁺@C₆₀ as compared with C₆₀ may result from the stronger electron acceptor ability of Li⁺@C₆₀, which facilitates the charge-transfer interaction as reported for the stronger charge-transfer binding of Li⁺@C₆₀ with corannulene.³⁰ Similarly the binding constant of the supramolecular complex of P(H₂P)₄ was determined from the spectral

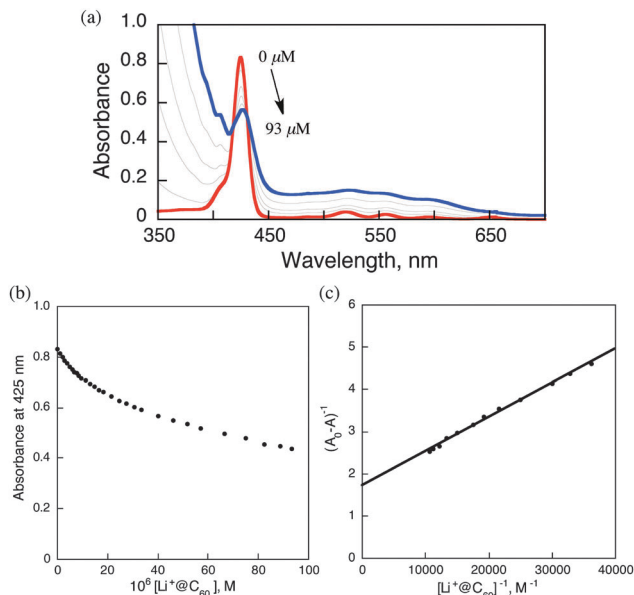

Fig. 2 (a) UV-vis absorption spectra of P(H₂P)₈ in the presence of various concentrations of Li⁺@C₆₀ in PhCN at 298 K; (b) absorption profile at 425 nm. (c) Benesi–Hildebrand plot for the determination of the association constant.

titration to be $6.2 \times 10^3 \text{ M}^{-1}$ (Fig. S1 in the ESI[†]). In the case of P(H₂P)₂ and P(H₂P)₁, however, the spectral change was too small to be able to determine the binding constants accurately (Fig. S2 and S3 in the ESI[†]). The binding constants are summarised in Table 1. Thus, multiporphyrins may facilitate charge-transfer interactions through the encapsulation of Li⁺@C₆₀ by multiple porphyrins.

Fluorescence of P(H₂P)₈ was quenched by the addition of a PhCN solution of Li⁺@C₆₀ as shown in Fig. 3a. A Benesi–Hildebrand plot for fluorescence quenching (Fig. 3b) afforded the apparent binding constant of the supramolecular complex of P(H₂P)₈ with Li⁺@C₆₀ being $8.5 \times 10^4 \text{ M}^{-1}$, which is significantly larger than the value determined from the absorption spectral titration ($2.1 \times 10^4 \text{ M}^{-1}$) (Fig. 2). Similarly the apparent binding constant of P(H₂P)₄ with Li⁺@C₆₀ was determined from the fluorescence quenching to be $1.6 \times 10^4 \text{ M}^{-1}$ (Fig. S4 in the ESI[†]), which is also larger than the value determined from the absorption spectral titration (Table 1). Such larger apparent binding constants determined from the fluorescence quenching than those determined from the absorption spectral titration

Table 1 Association constant (K , M^{-1}) of P(H₂P)_{*n*} with Li⁺@C₆₀ and C₆₀ in PhCN determined from UV-vis absorption and fluorescence spectral titration

| Porphyrin | Li ⁺ @C ₆₀ | | C ₆₀ ^b | |
|----------------------------------|----------------------------------|-------------------|--------------------------------|--------------------------------|
| | UV-vis | FL | UV-vis | FL |
| P(H ₂ P) ₁ | — ^a | 1.1×10^4 | — ^a | — ^a |
| P(H ₂ P) ₂ | — ^a | 1.1×10^4 | — ^a | — ^a |
| P(H ₂ P) ₄ | 6.2×10^3 | 1.6×10^4 | 2.7×10^3 ^b | 9.5×10^3 ^b |
| P(H ₂ P) ₈ | 2.1×10^4 | 8.5×10^4 | 5.3×10^3 ^b | 2.2×10^4 ^b |

^a Too small to determine accurately. ^b Taken from ref. 28.

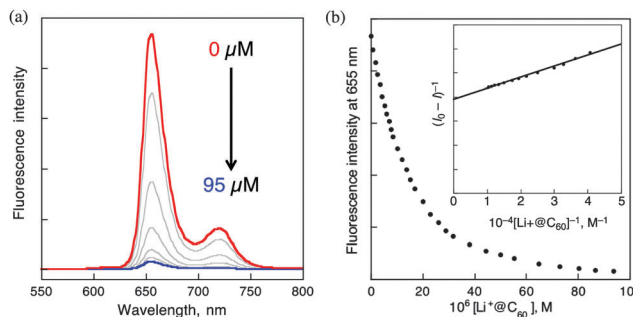

Fig. 3 (a) Fluorescence spectra of P(H₂P)₈ in the presence of various concentrations of Li⁺@C₆₀ in PhCN at 298 K; (b) fluorescence profile at 655 nm. Inset: Benesi–Hildebrand plot for the determination of the association constant.

indicate that energy migration occurs between the singlet excited state of H₂P (¹H₂P*) and adjacent H₂P in P(H₂P)_{*n*} (*n* = 4 and 8).

The energy migration rate constant was determined by the fluorescence lifetime measurements of P(H₂P)₈ with Li⁺@C₆₀. The fluorescence of ¹P(H₂P)₈* exhibited a single exponential decay with the lifetime of 11 ns. In the presence of Li⁺@C₆₀, the decay of ¹P(H₂P)₈* is well analysed by three exponentials with lifetimes of 100 ps, 3.0 ns and 11 ns. The fast component corresponds to the lifetime of ¹H₂P* in the supramolecular complex with Li⁺@C₆₀. 95% of the fast component agrees with that predicted by the binding constant determined from the absorption spectral titration. The third component has the same lifetime as that without Li⁺@C₆₀, corresponding to the fluorescence lifetime of ¹(H₂P)₈*. The second component corresponds to energy migration between ¹H₂P* and the adjacent H₂P. 5% of the sum of the first and second components agrees with that predicted from the binding constant determined from fluorescence quenching.

Femtosecond laser-induced transient absorption spectra of P(H₂P)₈ were recorded in the absence and presence of Li⁺@C₆₀ (Fig. 4 and Fig. S10 in the ESI[†]). In each case, only the singlet-singlet absorption of ¹P(H₂P)₈* was observed, because H₂P was exclusively excited at the excitation wavelength (425 nm) in Fig. 4. The decay of ¹P(H₂P)₈* exhibits a fast component with a lifetime of 6 ps. A similar fast component was observed for ¹P(H₂P)₄* and ¹P(H₂P)₂* (Fig. S11 in the ESI[†]). In the case of P(H₂P)₁, however,

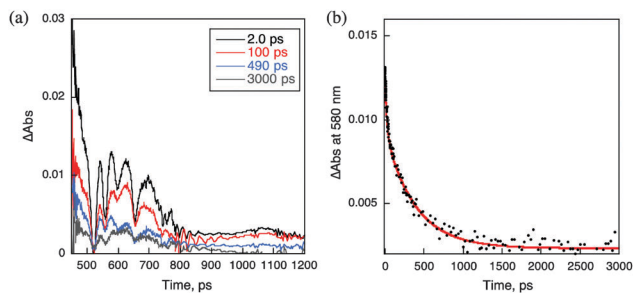

Fig. 4 (a) Transient absorption spectra of P(H₂P)₈ ($5.2 \times 10^{-6} \text{ M}$) with Li⁺@C₆₀ ($2.0 \times 10^{-5} \text{ M}$) in deaerated PhCN observed after femtosecond laser flash excitation. Excitation wavelength: 425 nm. (b) Decay time profile at 580 nm with a three-exponential decay curve fitting.

no fast component was observed (Fig. S6c in the ESI†). The ratio of the fast component increased upon increasing the number of H₂P in P(H₂P)_n. 96% of the fast component of P(H₂P)₈ decreased upon decreasing the laser intensity (Fig. 4b). These results indicate that the fast component results from the singlet-singlet annihilation of two ¹H₂P* moieties in P(H₂P)_n (n = 4 and 8).

In the presence of Li⁺@C₆₀ (20 μM), the decay of ¹P(H₂P)₈* exhibited three exponentials with lifetimes of 6 ps, 90 ps and 2 ns. The first fast component resulted from the singlet-singlet annihilation as observed without Li⁺@C₆₀. The second component (90 ps) may result from electron transfer from ¹H₂P* to Li⁺@C₆₀ in the supramolecular complex. Because the transient absorption due to the charge-separated state (H₂P^{•+} and Li⁺@C₆₀^{•-}) was not observed in Fig. 4a, where only the singlet-singlet absorption of ¹H₂P* is seen, back electron transfer may be much faster than the forward electron transfer. The third component may correspond to the energy migration between ¹H₂P* and the adjacent H₂P, because its lifetime agrees with the lifetime of energy migration in the fluorescence lifetime measurements. In the presence of high concentration of Li⁺@C₆₀ (120 μM), the component of electron transfer from ¹H₂P* to Li⁺@C₆₀ in the supramolecular complex increased. The three component decay was also observed for P(H₂P)₄ and P(H₂P)₂ with Li⁺@C₆₀ (Fig. S11 and S12 in the ESI†). In the case of P(H₂P)₁, only single exponential decay with a lifetime of 11 ns was observed in the absence and presence of Li⁺@C₆₀ because the binding of Li⁺@C₆₀ to P(H₂P)₁ was negligible.

Nanosecond laser-induced transient absorption spectra of P(H₂P)₈ with Li⁺@C₆₀ (40 μM) at the excitation wavelength of 532 nm are shown in Fig. 5, where the transient absorption band at 730 nm due to the triplet excited state of Li⁺@C₆₀ (³Li⁺@C₆₀^{*}) is observed together with the absorption band at 1035 nm due to Li⁺@C₆₀^{•-}.²⁵ The decay of the absorption at 730 nm coincides with the appearance of Li⁺@C₆₀^{•-} (Fig. S13 in the ESI†). Thus, electron transfer from P(H₂P)₈ to ³Li⁺@C₆₀^{*} occurs to produce the triplet charge-separated (CS) state of P(H₂P)₈^{•+} and Li⁺@C₆₀^{•-}. The transient absorption due to P(H₂P)₈^{•+} is overlapped with that of ³Li⁺@C₆₀^{*} in the 600–700 nm region. The photoexcitation of 532 nm resulted in the excitation of Li⁺@C₆₀ leading to the formation of ³Li⁺@C₆₀^{*} via intersystem crossing. The decay of the absorbance at 1035 nm due to Li⁺@C₆₀^{•-} obeyed first-order kinetics with the lifetime of 210 μs (Fig. 5b). Thus, back electron transfer from Li⁺@C₆₀^{•-} to P(H₂P)₈^{•+} occurs in the supramolecular complex. The lifetime is long because of the spin-forbidden back electron transfer in the triplet CS state.

Similarly the triplet CS states derived from ³Li⁺@C₆₀^{*} were observed for P(H₂P)_n (n = 4, 2, and 1) with Li⁺@C₆₀ (Fig. S14–S16 in the ESI†). The rate constants of electron transfer from ¹H₂P* to Li⁺@C₆₀ and the energy migration in the supramolecular complexes of P(H₂P)_n with Li⁺@C₆₀ are summarised in Table 2 together with the lifetimes of the triplet CS states. The CS lifetime increases upon increasing the number of H₂P in P(H₂P)_n. Such an increase in the CS lifetime may result from the charge migration between H₂P^{•+} and the adjacent H₂P in P(H₂P)_n^{•+}. The energy diagram of photoexcitation of P(H₂P)_n with Li⁺@C₆₀ is given

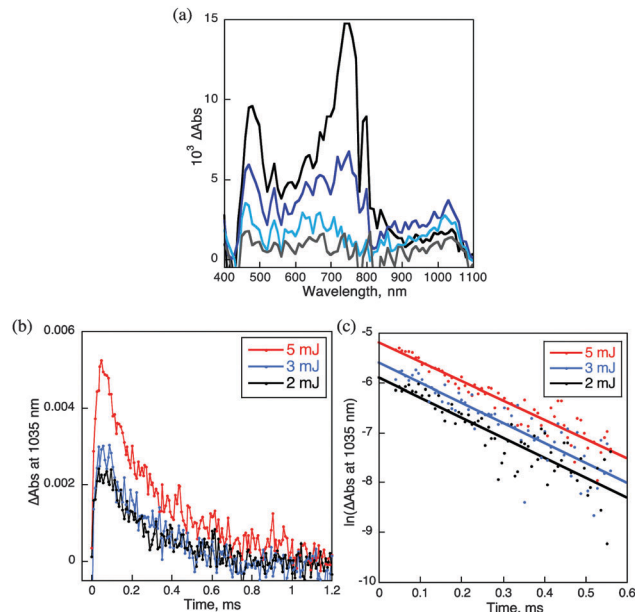

Fig. 5 (a) Transient absorption spectra of P(H₂P)₈ (2.6 × 10⁻⁶ M) with Li⁺@C₆₀ (4.0 × 10⁻⁵ M) in deaerated PhCN observed after nanosecond laser flash excitation taken at 8 (black), 32 (blue), 96 (sky blue) and 200 μs (gray). Excitation wavelength: 532 nm. (b) Decay time profile at 1035 nm with the different laser pulse intensities (2–5 mJ pulse⁻¹). (c) First-order plots.

| Porphyrin | P(H ₂ P) ₁ | P(H ₂ P) ₂ | P(H ₂ P) ₄ | P(H ₂ P) ₈ |
|---|----------------------------------|----------------------------------|----------------------------------|----------------------------------|
| <i>k</i> _{ET} , s ⁻¹ | 7.7 × 10 ⁵ | 6.7 × 10 ⁴ | 9.5 × 10 ⁴ | 1.5 × 10 ⁵ |
| <i>k</i> _e , M ⁻¹ s ⁻¹ | 1.7 × 10 ⁹ | 1.8 × 10 ⁹ | 8.0 × 10 ⁸ | 1.5 × 10 ⁸ |
| <i>τ</i> (CS), μs | — ^a | — ^a | 160 | 210 |
| <i>Φ</i> (CS) | 0.70 | 0.34 | 0.16 | 0.13 |

^a Bimolecular decay in the radical ion pair.

in Scheme 1. The energies of the excited state of porphyrin and Li⁺@C₆₀ were determined by UV-vis, fluorescence and phosphorescence spectral measurements. The energy of the CS state was determined to be 0.82 eV in PhCN from the one-electron oxidation potential of porphyrin (+0.96 V vs. SCE) and reduction potential of Li⁺@C₆₀ (+0.14 V vs. SCE) by the electrochemical measurements (DPV; see Fig. S17 in the ESI†). Femtosecond laser excitation of the supramolecular complex of P(H₂P)₈ with Li⁺@C₆₀ at 425 nm resulted in electron transfer from H₂P to the bound Li⁺@C₆₀ to produce the singlet CS state and energy transfer from ¹H₂P* to the adjacent H₂P, followed by electron transfer to Li⁺@C₆₀, when it is bound H₂P. The singlet CS state decays rapidly to the ground state. Nanosecond laser excitation at 532 nm resulted in the formation of the singlet excited state of excess Li⁺@C₆₀, followed by intersystem crossing to produce ³Li⁺@C₆₀^{*}, to which intermolecular electron transfer occurs from H₂P to produce the triplet CS state with a long lifetime because of the spin-forbidden back electron transfer to the ground state.

In conclusion, free base porphyrin polypeptides (P(H₂P)_n; n = 4 and 8) form supramolecular complexes with Li⁺@C₆₀ in PhCN,

Scheme 1 Reaction course of photoinduced charge separation and charge recombination in the supramolecular complex between $P(H_2P)_8$ and $Li^+@C_{60}$ with the values of energy levels.

in which the binding is much stronger than C_{60} . Efficient energy migration occurs between porphyrins in $P(H_2P)_n$. Although the lifetimes of the singlet CS states were too short to be detected, the triplet CS states derived from $^3Li^+@C_{60}$ had long lifetimes because of the spin-forbidden back electron transfer. The triplet CS lifetime becomes longer upon increasing the number of H_2P due to the charge migration among porphyrins. The present study provides valuable insight into the energy and electron transfer in multiple reaction centres.
