An acido- and photochromic molecular device that mimics triode action†

P. Remón,^a S. M. Li,^a M. Grøtli,^b U. Pischel^{*c} and J. Andréasson^{*a}

The photo-controlled shift of pH titration curves, describing the acidochromic behaviour of a spiropyran switch network, was harnessed for the realisation of a molecular triode. The intricate network can be correctly interpreted with respect to the pH dependence of the main involved species.

The fascinating opportunities offered by light-controlled molecular switches are currently unfolding in research areas such as chemical biology, nanochemistry, materials science, and molecular information processing.^{1–9} This preference is triggered by the possibility of changing molecular and system's properties by light exposure in a reversible, waste-free, non-invasive, and spatiotemporally controlled fashion. With a view on this, light has been increasingly used as a stimulus to devise molecular devices capable of performing logic operations^{5,10–14} with different degrees of complexity, *e.g.*, simple logic gates (AND, OR, NOR, *etc.*), elementary arithmetic operations (addition, subtraction), logic circuits (multiplexer, encoder, *etc.*), and memory devices.^{2,15–22}

In the semiconductor-driven world triodes/transistors play an archetypal role. Inspired by this, it is very appealing to devise molecules that are capable of mimicking the performance of these analogue electronic building blocks. Despite the conventional use of electrical signalling, chemical and photophysical phenomena can be interpreted along the lines of a molecular triode or transistor as well. One strategy is the exploitation of photochromic (dithienylethene) supramolecular systems for

the all-photonic realization of photo-controlled emission modulation *via* energy transfer.^{23,24} A different approach was followed using a pH-sensitive fluorophore, whose electron-transfer-induced emission quenching can be additionally controlled by metal cation complexation. The resulting pK_a shifts resemble the characteristics of triode *i*–*V* curves.²⁵ Finally, very recently the peculiar temperature-dependent operation of a fluorescent electrochemical switch was harnessed for demonstrating a transistor function.²⁶ Some of these systems require either intensive synthetic labour or a very specific chemical design. Others work with metal-cation inputs which may cause problems for the recycling of the function.

In an effort to base our chemical design on the generally and widely used class of photofunctional spiropyrans we came across a so far overlooked photo-controlled hysteresis effect in the pH titration curves describing the integrated acidochromic behaviour of such systems. Their application in bio-relevant contexts such as light-controlled DNA binding^{27–29} and interactions on proteins,³⁰ bioimaging,^{31–33} or biosensing³⁴ provides an additional incentive to explore their inherent functional character beyond the photochromic switching itself, for example for devising a molecular triode. This complements the conceptual importance of spiro-pyrans/-oxazines in molecular information processing as exemplified by molecular memories and Fuzzy logics.^{35–39}

Spiropyrans, such as the water-soluble **1**, are implied in photo- and acidochromic switching between three states: spiro form (SP), merocyanine (MC), and protonated merocyanine (MCH); Scheme 1.⁴⁰ In a very acidic solution (pH < 0.5) the protonated spiro form SPH is abundant, while the undesired hydrolysis of the MC form intervenes especially at basic pH (pH > 8).^{40,41} Therefore we limited our study to an intermediate pH window between 1.5 and 8.

In aqueous solution at pH ≥ 6 **1**SP is in thermal (“dark”) equilibrium with **1**MC ($K = k_1/k_2 = 0.16$ at pH 7) which can be displaced by protonation of the merocyanine to yield the thermally stable **1**MCH ($pK_a^I = 4.4$).⁴⁰ Hence, at high pH (pH ≥ 6) the SP form is dominant, whereas at low pH (pH ≤ 4.5)

the MCH form prevails. This is clearly manifested in the corresponding UV/vis absorption spectra (see Fig. 1). The small 1MC absorption band ($\lambda_{\text{max}} = 515$ nm) at pH 6 is contrasted by the dominating 1MCH absorption band ($\lambda_{\text{max}} = 416$ nm) at pH 3.

The situation changes dramatically when UV light ($\lambda = 254$ nm, power density of $700 \mu\text{W cm}^{-2}$) is applied until reaching the photostationary state (PSS). Now 1SP is photoisomerised to 1MC at $\text{pH} \geq 6$. The quantum yields (Φ) of the ring-opening and closing paths are 0.040 and 0.012, respectively.⁴⁰ However, at $\text{pH} \leq 4.5$ UV exposure culminates in the enrichment of the sample in 1SP; see Fig. 1. This is reasoned with the highly competitive ring closure of the 1MCH form to 1SP ($\Phi = 0.21$).

The photo-driven variation of the composition of the switch network has consequences for the titration curve monitoring the normalised concentration of the merocyanine form ($[1\text{MC}]/[1\text{MC}]_{\text{max}}$) depending on the pH; see Fig. 2. 1MC can be conveniently followed by its absorbance at $\lambda = 515$ nm, where none of the other forms of **1** absorb. In the absence of light irradiation, the concentration of 1MC is mainly determined by the degree of protonation producing 1MCH. However, as described above,

Fig. 1 UV/vis absorption spectra of **1** (20 μM in water) for the thermal equilibrium (pH 3, black full line; pH 6, red full line) and in the PSS (pH 3, black dashed line; pH 6, red dashed line).

Fig. 2 pH titration curves monitoring the normalised 1MC concentration ($[1\text{MC}]/[1\text{MC}]_{\text{max}}$). The experimental data points were obtained for fully equilibrated systems (i.e. thermal equilibrium and/or PSS). Colour codes: red = absence of irradiation (dark reaction); black = irradiation with 254 nm light; blue = irradiation with 254 nm light with an attenuated UV intensity (to 1.3%). The lines correspond to sigmoid fits for guiding the eye.

1MCH is efficiently photo-converted to 1SP and thereby removed from the protonation equilibrium involving 1MC. Consequently, the re-establishment of the thus disturbed equilibrium leads to a decreased relative 1MC concentration as compared to the same pH in the absence of UV irradiation. This is experimentally expressed in a positive shift of the “apparent pK_a ” value by about 1.6 units. Note that this shift is the result of the integrated behaviour of the switch network and conceptually different from the observation of pK_a shifts on photo-conversion between two isomers with differing basicity.^{42,43}

Furthermore it was foreseen that the irradiation with an attenuated UV intensity would reveal an intermediate situation, signalled by a pH titration curve situated between the two beforehand discussed cases (thermal processes and irradiation at full UV intensity). Gratifyingly this was indeed verified for an attenuation to 1.3% of full UV intensity; see Fig. 2.

The working principle and characteristics of a triode can be described as follows. Upon heating the cathode by a filament a thermoionic emission of electrons results, which is collected by a positively charged anode plate. On their way the electrons have to pass through a grid which acts like a gate. The anode current-voltage (i_A - V_A) curve can be shifted by the variation of the grid voltage (V_G), resulting in the situation shown in Fig. 3. The comparison of these electronic characteristics with the herein observed shift of the pH titration curve allows the drawing of analogies. In our molecular version the triode produces an output in the form of 1MC concentration, which is varied by pH and UV intensity, corresponding to i_A , V_A , and V_G , respectively.

Based on the relevant rate- and protonation constants, the pH titration curve monitoring the concentration of 1MC was modelled and it showed virtually quantitative agreement with the experimental data (see ESI†). The discussed intricate interplay between the different forms of the network was further validated by monitoring the 1SP and 1MCH forms. Their observation is not directly linked to the readout of the absorbance at a specific

Fig. 3 Characteristic i - V curves of a triode upon variation of the grid voltage (V_G). The inset shows the electronic representation of a triode and the assignment of the applied potentials.

wavelength as their absorption spectra overlap significantly. Therefore a system of equations that allows the numerical calculation of their concentrations was developed (see ESI†). Expectedly and in accordance with the corresponding modelling, monitoring the normalised concentration of 1MCH revealed opposite pH dependence compared to that established for 1MC, see ESI†. Finally, also the plot of the normalised concentration of 1SP confirmed the applied lines of thought. Interestingly, but not unexpectedly, the titration curves for 1SP are not shifted but inverted (Fig. 4). In the absence of irradiation, the SP concentration is elevated at high pH (the 1SP/1MC equilibrium is on the side of the ring-closed SP form; see above) and diminished at low pH (mostly due to the shifted equilibrium caused by the formation of the thermally stable 1MCH). However, under irradiation this is inverted: the relative concentration of 1SP is high at low pH (due to the efficient 1MCH \rightarrow 1SP conversion) and low at high pH (due to the 1SP \rightarrow 1MC conversion). Curiously, the application of attenuated UV intensity balances the network in such a way that virtually no pH dependence of the relative 1SP concentration is observed.

Fig. 4 pH titration curves monitoring the normalised 1SP concentration ($[1SP]/[1SP]_{\max}$) in the dark (red), under full UV irradiation (254 nm; black) or attenuated UV irradiation (to 1.3% of full intensity; blue). The data were obtained under equilibrium conditions (i.e., thermal equilibrium and/or PSS). The sigmoid curves are meant to guide the eye.

In conclusion, the herein discovered photo-controlled shift of the pH titration curve, describing the acidochromic behaviour of the water-soluble spirocyan 1, can be harnessed for the design of a molecular triode. The output of this device is read through the exclusive absorption signal of the MC form at 515 nm and the grid voltage is presented by the UV intensity. The described effects open the door to integrate the triode function with other features that can be introduced for example on the synthetically flexible indole nitrogen position.

Financial support from the Spanish *Ministerio de Economía y Competitividad* (grants CTQ2011-28390 and CTQ2014-54729-C2-1-P for U. P.), the *Junta de Andalucía* (P12-FQM-2140), FEDER, and the Swedish Research Council VR (grant 622-2010-280 for J. A.) is gratefully acknowledged.
