Base-free oxidation of glucose to gluconic acid using supported gold catalysts†

Yueling Cao,^{abc} Xi Liu,^a Sarwat Iqbal,^a Peter J. Miedziak,^a Jennifer K. Edwards,^a Robert D. Armstrong,^a David J. Morgan,^a Junwei Wang^b and Graham J. Hutchings^{*a}

1% Au/TiO₂ catalysts prepared by a range of preparation methods were studied for the base-free oxidation of glucose. The highest catalytic activity was observed with the catalyst prepared by the sol-immobilization method. Furthermore we have studied the effect of the post-synthesis treatments of treatment with water, or heating in air on the activity. The catalyst calcined at 250 °C showed optimal activity and selectivity. Additionally, we studied the effect of the amount of stabilising ligand in the sol-immobilisation method and observed that this is a key parameter with respect to determining the catalyst's activity.

Introduction

At present, there is a large amount of interest in the use of carbohydrates as chemical feedstocks due to their renewability and abundance.^{1–4} D-Gluconic acid, derived from the oxidation of D-glucose, is a useful food additive and raw material for the manufacturing of medicines and biodegradable polymers.^{5–7} Currently, gluconic acid and its salts are produced industrially by the enzymatic oxidation of D-glucose.⁸ However, there are a number of drawbacks to this process including maintenance of enzyme activity, slow reaction rates and the disposal of the microbes following use.^{9–12} The main barrier to large-scale application of these fermentation processes is the requirement for a neutralisation step which prevents deactivation of the enzymes by the acidic products.¹² A promising alternative to the enzymatic route is the direct oxidation using a heterogeneous catalyst with molecular oxygen as the oxidant. Comotti *et al.* have reported the oxidation of glucose both with and without hydrogen peroxide,¹³ there are also a number of other reports of heterogeneous catalysts, including supported Pd, Pt, Bi-Pd, Bi-Pt, Au, Au-Pd and Au-Pt nanoparticles.^{14–19} However strict pH control is required to obtain high rates of glucose conversion and this is achieved by the addition of a sacrificial base, typically sodium hydroxide.^{20–22} Therefore, from the viewpoint of green

chemistry, there is a need to develop heterogeneous catalysts that can catalyse the oxidation of glucose under base-free conditions. Of the reported catalysts, Au catalysts exhibit the ability to catalyse the oxidation of glucose without pH control, thus allowing the production of gluconic acid, rather than its salt.^{17,19,23,24} More importantly, it has been demonstrated that, under such conditions, it is possible for the combination of acid-catalysed hydrolysis reactions and Au-catalysed glucose oxidation to occur in a single reaction vessel.^{25–27} Such catalytic cascade reactions are important for the conversion of disaccharides, oligosaccharides and cellulose into gluconic acid. Recently we have reported an Au/MgO catalyst for the selective synthesis of gluconic acid from glucose under mild reaction conditions.²⁴

It is well known that the activity and/or selectivity of Au catalysts is strongly dependent on several parameters such as morphology, dispersion and the interaction between the Au nanoparticles and the support (where present).^{28–31} According to previous reports, the particle size appears to be the most important parameter with respect to the activity and selectivity in reactions catalysed by Au.^{21,32,33} However, the preparation method for supported Au nanoparticles is a key factor in the synthesis of size- and structure-controlled nanoparticles. Furthermore, the synthesis of highly dispersed small Au particles is highly sensitive to any thermal pretreatment. Unfortunately, the results reported in the literature concerning these factors are often contradictory.^{9,34,35} Therefore, a detailed study of the influence of preparation conditions is necessary to ensure that we can obtain highly active Au catalysts reproducibly. The aim of the current study is to investigate the influence of the preparation method on Au/TiO₂ catalysts for the base-free aqueous phase oxidation of glucose. TiO₂ was selected as the support as it is more

stable, as compared to MgO, under the base-free reaction conditions.³⁶

Experimental methods

Catalyst preparation

a. Conventional impregnation method (CIM). The catalysts were prepared using the procedure which has been reported previously.³⁷ In a typical synthesis of a 1% Au/TiO₂ catalyst, the requisite amount of TiO₂ (Degussa Evonik P25) was added to the aqueous solution of HAuCl₄·3H₂O (HAuCl₄·3H₂O Sigma Aldrich, 11.5 mg L⁻¹) with vigorous stirring. The solution was agitated in this way until it formed a paste, which was dried (110 °C, 16 h) and calcined in static air, typically at 250 °C for 3 h.

b. Modified impregnation method (MIM). 1% Au/TiO₂ was prepared by a modified impregnation method as described previously.³⁸ An aqueous solution of HAuCl₄·3H₂O (Sigma-Aldrich, 11.5 mg L⁻¹) was stirred at 1000 rpm, and the temperature was raised from room temperature to 60 °C over a period of 10 min. TiO₂ (Degussa Evonik P25) was added slowly over a period of 8–10 min with constant stirring. The slurry was stirred at 60 °C for 15 min. The temperature of was raised to 95 °C for 16 h to give a dry solid was ground and calcined in static air (250 °C, 3 h).

c. Deposition–precipitation method (DP). In a typical synthesis of a 1 wt% Au/TiO₂ catalyst the requisite amount of an aqueous solution of HAuCl₄·3H₂O (Sigma-Aldrich, 11.5 mg L⁻¹) was added to a slurry of TiO₂ (Degussa Evonik P25) in water. This solution was stirred at room temperature for 10 min, and then an aqueous solution of NaOH was added drop wise until the pH of the solution reached 9. The solution was stirred and maintained at pH 9 for 60 min. The catalyst was then washed, filtered, dried (110 °C, 16 h) and calcined in static air (250 °C, 3 h).

d. Sol-immobilization method (SIM). 1% Au/TiO₂ was prepared using the procedure which has been reported previously.³⁹ An aqueous solutions of HAuCl₄·3H₂O (Sigma-Aldrich, 11.5 mg L⁻¹), polyvinylalcohol (PVA) (1 wt%, Aldrich, M_w = 10 000, 80% hydrolyzed) and NaBH₄ (0.1 M) were prepared. The requisite amount of a PVA solution was added to an aqueous Au solution. The freshly prepared solution of NaBH₄ was then added to form a dark-brown sol. After 30 min of sol generation, the colloid was immobilized by adding TiO₂ (Degussa P25). A small amount of H₂SO₄ was added under vigorous stirring to attain a pH of 1–2. After 2 h, the slurry was filtered, and the catalyst was washed thoroughly with distilled water (2 L) until the filtrate was neutral and then dried at (110 °C, 16 h, static air).

Catalyst post-synthesis treatment

a. Reflux method. The dried 1% Au/TiO₂ (SIM) was treated with hot water.⁴⁰ Typically, catalyst (1 g) was heated at 90 °C in water (150 mL) with stirring (1000 rpm for 60 min). The catalyst was recovered by filtration and washed with distilled water (2 L) and dried (110 °C, 16 h).

Table 1 Effect of catalyst preparation method of 1 wt% Au/TiO₂ on the oxidation of glucose

Preparation method	Conversion (%)	Yield (%)		
		Gluconic acid	Fructose	5-HMF
CIM	30.3	20.0	4.6	Trace
MIM	22.8	5.3	9.8	0.1
DP	61.7	58.0	2.5	Trace
SIM	71.1	67.3	Trace	Trace

Reaction conditions: glucose 0.20 g, water 20.0 g, catalyst 0.05 g, reaction temperature 160 °C, reaction time 1 h, O₂ 3 bar.

b. Heat treatment. The dried 1% Au/TiO₂ (SIM) catalyst was calcined in static air at 250, 350, 450, and 550 °C for 3 h.

Catalyst characterization

X-ray photoelectron spectroscopy (XPS). XPS measurements were carried out using a Kratos Axis Ultra DLD spectrometer using monochromatic AlK α radiation operating at 144 W (12 mA $\times$ 12 kV) and pass energies of 40 and 160 eV for high resolution and survey scans respectively. Samples were mounted using double-sided adhesive tape. Data analysis was performed in CasaXPS v2.3.17 after charge correction to the Ti2p_{3/2} line (458.2 eV) and utilizing sensitivity factors supplied by the instrument manufacturer.

X-ray diffraction (XRD). Powder X-ray diffraction (XRD) patterns were recorded using a Panalytical X'pert Pro diffractometer using Ni filtered CuK α radiation (operating at 40 kV, 40 mA). Scans were in the range of 10–80° 2 θ .

Transmission electron microscopy (TEM). Transmission electron microscopy (TEM) was carried out using a Jeol 2100 with a LaB₆ filament operating at 2000 kV. Samples were prepared by dispersing the powder catalyst in ethanol and dropping the suspension onto a lacey carbon film over a 300 mesh copper grid.

Fig. 1 XRD pattern of 1% Au/TiO₂ catalysts prepared with different methods.

Fig. 2 Representative TEM images and associated particle size distributions for 1% Au/TiO₂ prepared by a) CIM, b) SIM and c) DP. Particle size distributions based on 300 particles.

Glucose oxidation

Reactions were carried out using a low pressure Colliver glass reactor (50 ml). Glucose (0.20 g), catalyst (0.05 g) and water

(20 g) were added into the reactor, which was then purged with oxygen three times before the reactor was sealed and pressurized with oxygen (3 barg). The reaction mixture was

heated to 160 °C for 1 h under constant stirring (1000 rpm), then cooled to room temperature and the products analyzed by HPLC using an Agilent 1200 fitted with a metacarb 67H column, and UV and RI detectors.

Results and discussion

The effect of the catalyst preparation method on base-free glucose oxidation

1% Au/TiO₂ catalysts prepared using the four methods were tested for the base free oxidation of glucose and the data is shown in Table 1. All of the catalysts were calcined in static air (250 °C, 3 h) before reaction. It is apparent that the preparation method has a marked effect on the catalyst performance with the SIM catalysts giving the best performance.

The catalysts were characterized using XRD, XPS and TEM to determine the possible origin of the differences in catalyst performance we observed. The XRD patterns of the catalysts prepared by the different methods are shown in Fig. 1. The reflections associated with the Au (200), Au (220) and Au (311) (ICDD 00-004-0784) were observed in the samples prepared by the CIM. 1% Au/TiO₂ prepared by MIM, presented two major reflections at $2\theta = 44.4^\circ$ and 64.7° , which are characteristic of the Au (200) and (220) phase respectively. No clear reflections associated with Au were present in the samples prepared by DP and SIM.

Based on the XRD results it is apparent that the Au particles obtained from SIM and DP were considerably smaller than those obtained from CIM. To confirm this we examined the SIM, DP and CIM catalysts by TEM. Fig. 2a–c shows representative images and the associated particle size distributions for the CIM, SIM and DP catalysts respectively. The average particle sizes observed inversely correlate with the activity data shown in Table 1. The DP and SIM catalysts showed a similar particle size distribution with the average particle size significantly smaller than that of the CIM catalyst. This is in agreement with the XRD data as even the largest particles observed in the SIM and DP catalysts are *ca.* 7 nm, which would be below the XRD detection limit given the low concentration of metal in the samples.

Although the largest particles observed in the CIM catalyst by TEM were *ca.* 9 nm, the XRD suggested that larger metal particles were also present in this catalyst. In our previous studies we found that the CIM method showed a bimodal particle size distribution with small (2–10 nm) and large (>20 nm) metal particles in the final catalyst.⁴¹

XPS spectra for Au (4f) and Cl (2p) for 1% Au/TiO₂ samples prepared by the four different methods are shown in Fig. 3.

Compared with the catalysts prepared by SIM and DP, the Au signal intensity of catalysts prepared by CIM and MIM was significantly lower suggesting that poorly dispersed particles are present in these catalysts, despite the

Fig. 3 Au(4f) and Cl(2p) spectra for 1% Au/TiO₂ samples prepared by different methods.

smaller Au particle size suggested by the lower binding energy observed. For the catalysts prepared by the SIM and DP methods, no obvious signal associated with Cl (2p) can be detected, while Cl (2p) peaks are apparent for the samples obtained by CIM, and MIM methods. This can be further confirmed by the surface concentrations determined by XPS of a number of elements present in 1% Au/TiO₂

Table 2 Effect of the catalyst post treatment on 1% Au/TiO₂ for the base-free oxidation of glucose

Treatment condition	Conversion (%)	Yield (%)		
		Gluconic acid	Glucaric acid	Glycolic acid
None	31.8	28.7	None	None
Air, 250 °C	71.1	67.3	Trace	None
Water	66.4	63.8	Trace	Trace

Reaction conditions: glucose 0.20 g, water 20.0 g, catalyst 0.05 g, reaction temperature 160 °C, reaction time 1 h, O₂ 3 bar.

catalysts prepared with different methods (ESI† Table S1). The variation in the amount of surface metals is not unexpected as the SIM and DP methods contain a washing step,

whereas the CIM and MIM methods do not. For the catalysts prepared by CIM and MIM, the residual chloride was determined to be 0.77 wt% and 0.58 wt%, respectively. It is

well known that residual chloride can affect catalytic activity in two different ways: (a) by facilitating the agglomeration of Au particles during heat treatment and (b) through poisoning of the active site.⁴² We therefore conclude that the large Au particle size and amount of residual chloride are the two main factors which contribute to the low catalytic activity with the CIM and MIM catalysts for this reaction.

Effect of the catalyst post-synthesis treatment on base-free oxidation of glucose

When using the SIM method, part of the excess PVA used in the synthesis process can be removed either by a solvent washing step or through a heat treatment.⁴³ However, part of the PVA still remains and requires further treatment.⁴⁴ Therefore, thermal treatment (calcination at 250 °C for 3 h under static air) and a hot water washing method were used in an attempt to remove more of the PVA. The results for the post-treated catalysts for the base-free oxidation of glucose are shown in Table 2.

The dried only sample exhibited 31.8% glucose conversion, whereas the activity increased to 71.1% and 66.4% after calcination and treatment with water respectively. It is possible that these treatments induce structural changes within the Au catalysts, indeed calcination has been previously reported to lead to changes in particle size.⁴⁰ However, from XRD and XPS surface analysis (ESI† Fig. S1 and S2, Table S2), there was no obvious difference between dried and treated samples, TEM analysis (Fig. 4) showed that there is a small increase in the average particle size, however, this is not marked enough to be observable by XRD or XPS. As the difference in particle size observed was small we consider that additional factors may affect the change in catalytic activity. Additionally, the 1% Au/TiO₂ prepared by DP showed similar activity for glucose conversion, which may further imply that the residual PVA is blocking the active site through steric effects. Villa *et al.*, have reported that the presence of PVA can lower the activity of Au/TiO₂ thorough shielding of the Au nanoparticles.⁴⁴ From the increase in the activity shown in Table 2 we conclude that both calcination and reflux treatments are efficient ways to enhance the catalytic activity of SIM catalysts for base free glucose oxidation. However, as the highest activity was observed for the calcined SIM catalyst we decided to investigate this further. The effect of calcination temperature on the activity of the 1% Au/TiO₂ SIM catalyst is shown in Table 3. As expected, the catalytic activity initially increased with calcination temperature reaching a maximum at 250–350 °C, then decreased gradually at 450 and 550 °C. This may be due to a compromise at the lower calcination temperatures where some PVA was removed, but not resulting in a significant increase in particle size from sintering. However, when the calcination temperature was further increased the Au particle size became too large and a decline in activity was observed.

Table 3 Effect of calcination temperature on 1 wt% Au/TiO₂ catalyst

Calcination temperature (°C)	Conversion (%)	Yield (%)		
		Gluconic acid	Glucaric acid	Glycolic acid
None	31.8	28.7	None	None
250	71.1	67.3	Trace	None
350	69.0	65.4	Trace	Trace
450	59.2	53.8	Trace	Trace
550	46.3	41.6	Trace	Trace

Reaction conditions: glucose 0.20 g, water 20.0 g, catalyst 0.05 g, reaction temperature 160 °C, reaction time 1 h, O₂ 3 bar.

The XRD patterns of 1% Au/TiO₂ prepared by the SIM method, calcined at different temperatures, are shown in Fig. 5. The sample calcined at 550 °C presented one weak reflection at 44.4°, which can be attributed to the Au (200) phase. This suggests that there was a significant particle growth at this high calcination temperature. As a result, thermal treatment can be a challenging trade-off between the elimination of the stabilizer and undesirable structural changes to the final catalysts.

TEM analysis was also carried out on these catalysts, representative images are shown in Fig. 6 and the associated particle size distributions (PSDs) are shown in Fig. 7. As previously discussed calcination at 250 °C resulted in larger particles; however, as shown in Fig. 7 increasing the temperature to 350 °C resulted in a significant increase in particle size. The particle size was similar for the catalyst calcined at 450 °C, but increased when the calcination temperature was raised to 550 °C. This correlates well with the activity data shown in Table 3. It is clear that two factors can influence the activity namely the removal of the PVA by calcination and the increase in the average particle size which need to be balanced against each other.

Fig. 5 XRD patterns of 1% Au/TiO₂ catalysts calcined at different temperatures.

Fig. 6 Representative TEM images of 1% Au/TiO₂ SIM calcined at a) 250 °C, b) 350 °C, c) 450 °C and d) 550 °C.

Effect of the PVA to Au ratio in the SIM preparation method

To investigate the balance between the influence of particle size and the possible ligand shielding effect we prepared 1% Au/TiO₂ SIM catalysts using six PVA/Au weight ratios of 0, 0.05, 0.1, 0.6, 1.2 and 1.8. We considered the ratio of PVA to Au to be a key factor in affecting the catalytic activity as it can change both the amount of residual PVA and the metal particle size. To avoid the influence of heat treatment on the residual stabilizer and Au particle size the catalysts were prepared without further heat treatment after the drying step. The results of the effect of ratio of PVA to Au on the base-free oxidation of glucose are presented in Table 4 and reveal a volcano-type correlation for activity with the ratio of PVA to Au. The maximum activity was observed for the PVA to Au ratio of 0.1. When the ratio of PVA to Au was lower than this, the activity of catalysts decreased which may be due to a large particle size resulting from there being insufficient PVA to form colloids.⁴⁵ However, when the ratio of PVA to Au was higher than 0.1, the activity of catalysts gradually decreased which was most likely due to the presence of PVA blocking active sites. This behavior is similar to what has been previously reported for PVA stabilized Au nanoparticles supported on activated carbon and TiO₂.⁴³

Having found the optimum PVA/Au ratio we compared the performance of SIM catalysts with and without heat treatment (ESI† Table S3). For the dried only and calcined catalysts, the glucose conversion and gluconic acid yield were 88.4%, 89.9% and 84.0%, 86.2%, respectively. This indicates that the thermal treatment did not affect the catalytic activity when the optimum ratio of PVA to Au was used in the SIM preparation method, because there was insufficient stabilizer to create the shielding effect and therefore the removal by heat treatment did not affect the activity. Taken together, it can be concluded that the preferred weight ratio of PVA to Au is 0.1 in the preparation of Au/TiO₂ catalysts by the SIM method for the base free oxidation of glucose.

To confirm this trend these catalysts were characterized in greater detail. XRD results (ESI† Fig. S3) did not show any difference between the catalysts. XPS was performed to explore the possibility of an electronic effect between Au and PVA. As shown in Fig. 8 the binding energy of Au(4f) increased with an increasing PVA/Au ratio. This may be due to the change in electronic structure as a function of cluster size, which is in agreement with previous studies, which attributed an upward shift in the Au(4f) binding energy to increasing particle size.⁴⁶

Fig. 7 Particle size distribution for 1% Au/TiO₂ SIM calcined at a) 250 °C, b) 350 °C, c) 450 °C and d) 550 °C.

Table 4 Effect of PVA to Au ratio (w/w) on catalytic activity of 1 wt% Au/TiO₂ catalyst

PVA : Au (weight ratio)	Conversion (%)	Yield (%)		
		Gluconic acid	Glucaric acid	Glycolic acid
0	62.9	60.3	Trace	Trace
0.05	62.5	60.8	Trace	Trace
0.1	88.4	84.0	Trace	0
0.6	57.6	54.2	Trace	0
1.2	31.8	28.7	0	0
1.8	26.7	10.7	0	0

Reaction conditions: glucose 0.20 g, water 20.0 g, catalyst 0.05 g, reaction temperature 160 °C, reaction time 1 h, O₂ pressure 3 bar.

TEM particle size distributions (Fig. 9) of three of the catalysts confirm these conclusions. The most active catalyst (PVA/Au = 0.1) had an average particle size of 7.6 nm,

Fig. 8 Au(4f) spectra for 1% Au/TiO₂ SIM samples prepared with different ratio of PVA to Au (w/w).

Fig. 9 Representative TEM images and associated particle size distributions for 1% Au/TiO₂ prepared by SIM with different PVA : Au ratios a) 0.1, b) 1.2 and c) 1.8. Particle size distributions based on 300 particles except for a) where 100 particles were counted.

whereas the catalysts with higher ratios, namely 1.2 and 1.8 both had average particle sizes of around 2.1 nm. Surprisingly, the large particles, which we would expect to be less

active, were more active than the smaller particles. This further confirms that the role of PVA in shielding the active sites is significant for this reaction.

Conclusions

We have shown that Au/TiO₂ catalysts are active and selective for the oxidation of glucose to gluconic acid under base-free conditions. Among the different methods for preparing the Au catalysts, sol-immobilization is considered to be the favoured way to obtain Au catalysts that give high catalytic activity in this reaction. The pretreatment of catalysts has a significant influence on their catalytic activity, and the Au particle size is also shown to be an important factor.

We have found that the catalytic activity is affected by a combination of factors, the most significant amongst them being the metal particle size and the amount of PVA stabilizing ligand used in the SIM method. The most active catalyst observed did not have the smallest particle size, but did use one of the lowest PVA to metal ratios in their preparation. This suggests that the amount of residual ligand is the most significant factor in determining catalytic activity. We also show that activity can be improved through the removal of the ligand using either heat treatment or refluxing, though it is preferable to minimize the amount of ligand used during the preparation. When the optimum amount of ligand was used, post preparation treatments were observed to have no significant effect upon the resulting catalytic activity or selectivity.
