# A radical addition/cyclization of diverse ethers to 2-isocyanobiaryls under mildly basic aqueous conditions $\dagger$ 

Cintia Anton-Torrecillas, Diego Felipe-Blanco and Jose C. Gonzalez-Gomez*

#### Abstract

Mildly basic aqueous conditions facilitated the tert-butyl peroxybenzoate (TBPB) mediated dehydrogenative addition of a range of ethers, including acetals, to diverse substituted 2 -isocyanobiaryls. Mechanistic studies suggest that this radical cascade is an example of base promoted homolytic aromatic substitution (BHAS).

## Introduction

Phenanthridine is the scaffold of many naturally occurring products ${ }^{1}$ that exhibit a wide range of bioactivities, such as antitumor, ${ }^{2}$ antituberculosis, ${ }^{3}$ antimicrobial, ${ }^{4}$ antiviral, ${ }^{5}$ acaricidal, ${ }^{6}$ and fungicidal activities. ${ }^{7}$ Some phenanthridine derivatives have also found application in biological chemistry as dyes for cytofluorometric assays ${ }^{8}$ or even in materials science due to their optoelectronic properties. ${ }^{9}$ Recently, the assembly of the phenanthridine framework has been elegantly achieved with a cascade that involves the addition of radicals to somophilic 2-isocyanobiphenyls, followed by intramolecular homolytic aromatic substitution. ${ }^{10,11}$ In this context, and given the progress made in the $\mathrm{C}_{\alpha}-\mathrm{H}$ oxidation of ethers with peroxides to form radicals, ${ }^{12}$ the oxidative addition of ethers to 2-isocyanobiphenyls has been successfully achieved using different conditions. ${ }^{13}$ This transformation requires a dual selective $\mathrm{C}-\mathrm{H}$ bond functionalization, and constitutes a powerful tool to increase molecular complexity with high atomeconomy, where only hydrogen is lost (Scheme 1). Moreover, ethers are very important raw materials and they are also common substructures of natural and synthetic bioactive products. ${ }^{14}$ Consequently, the development of methods that make use of relatively unreactive ethers to build complex molecules, is highly demanded by organic and medicinal chemists.

It is worth noting that 1,4-dioxane is the model substrate for $\mathrm{C}-\mathrm{H}$ bond functionalization of ethers in most of the reported studies. ${ }^{13}$ This symmetric ether presents all eight $\mathrm{C}-\mathrm{H}$ bonds adjacent to an oxygen atom, which stabilizes the

radical by hyperconjugation with the non-bonding electrons. Moreover, theoretical studies suggest that the release of ring strain upon radical formation is greater in 1,4-dioxane than in other cyclic ethers such as tetrahydrofuran. ${ }^{15}$ As a matter of fact, when TBPB was used as the oxidant in the insertion of 2-isocyanobiaryls with ethers, only 1,4-dioxane was successful and THF failed. ${ }^{13 a}$ Notably, when benzoyl peroxide was used in the same transformation, another three ethers could be inserted with moderate results (40-45\%). ${ }^{13 b}$ To the best of our knowledge, the greatest number of ethers tolerated in this reaction (seven examples) has been possible with the use of DTBP as the oxidant, $\mathrm{FeCl}_{3}$ as the catalyst and DBU as the cocatalyst. ${ }^{13 c}$ With these precedents we decided to develop a new protocol for this reaction aimed at accommodating a range of ethers, free of transition-metal catalysts and using economical and environmentally friendly conditions (Scheme 2).

## Results and discussion

To explore new reaction conditions we selected 2-isocyanobiphenyl (1a) and THF (2a) as model substrates. In a control experiment we performed the reaction using BPO as the oxidant at $100{ }^{\circ} \mathrm{C}$ and we obtained $35 \%$ yield of the desired

Scheme 2 Previous results and our reaction conditions for THF.
product 3aa, a similar result to the one obtained by the Cheng group, ${ }^{13 b}$ together with byproduct $\mathbf{4 a}$ (Table 1, entry 1). Surprisingly, the addition of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and $\mathrm{H}_{2} \mathrm{O}$ completely inhibited the formation of 3aa (entry 2). Prompted by the excellent results in oxidative transformations achieved with $\mathrm{Bu}_{4} \mathrm{NI}$ as the catalyst and TBHP, ${ }^{16}$ we tried this combination, but 3aa was obtained in low yield (entry 3). The use of DTBP or $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{~S}_{2} \mathrm{O}_{8}$ in combination with $\mathrm{Bu}_{4} \mathrm{NI}$ was also unsuccessful in this transformation (entries 4-6). It is reported that TBPB fails to afford product 3aa in this reaction and that only compound $\mathbf{4 a}$ is obtained. ${ }^{13 a}$ To our surprise, the inclusion of $\mathrm{H}_{2} \mathrm{O}$ in this reaction mixture afforded product 3aa, although in low yield (entry 7). We were pleased to find that the same oxidant, but in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and $\mathrm{H}_{2} \mathrm{O}$, allowed full conversion of 1a to obtain compound 3aa in good yield (entry 10). While the addition of $\mathrm{Bu}_{4} \mathrm{NI}$ had no important impact on the reaction, the amount of base and the control of the reaction temperature were crucial to obtain good and reliable results (entries

[^1]$8-11)$. Similar results were obtained with $\mathrm{Na}_{2} \mathrm{HPO}_{4}$, and lower yields were obtained for the desired product when non-nucleophilic organic bases were used in substoichiometric amounts (entries 12-14).

Having found very simple optimized conditions for the model reaction, we evaluated its scope using different 2-isocyanobiaryls and THF (Scheme 3). We first examined substrates with substituents on the upper aromatic ring. Methyl-substituted products 3ba and 3ca were obtained in good to moderate yields, without observing any benzylic oxidation. During the formation of 3ca, some compound 3aa was also observed (GC-MS), likely by ipso-homolytic aromatic substitution, and its isolated yield was affected due to difficulties in the chromatographic purification. A more electron-donating group such as methoxy was compatible with this protocol, affording compound 3da in reasonably good yield, as well as the corresponding byproduct $4 \mathbf{d}$ (detected by GC-MS and ${ }^{1} \mathrm{H}-\mathrm{NMR}$ ).

When 2-(2-isocyanophenyl)-naphthalene was used, compound 3ea was the only regioisomer isolated in moderate yield, despite the steric hindrance between the ether moiety and the extra aromatic ring. ${ }^{17}$ Electron-withdrawing groups, such as acetyl, trifluoromethyl, chloro and fluoro, were suitable substituents in the upper aromatic ring, furnishing products (3fa, 3ga, 3ha and 3ia) in good isolated yields. Interestingly, when meta-substituted substrates $\mathbf{1 j}$ and $\mathbf{1 k}$ were used, both possible regioisomers were isolated after column chromatography. While the ratio of $\mathbf{3 j} \mathbf{j} / \mathbf{3} \mathbf{j} \mathbf{j}$ was $1: 1$, for $\mathbf{1 k}$ the major product was the most crowded regioisomer (3ka). ${ }^{18}$ We also examined isocyanobiaryls substituted in the lower aromatic ring by elec-tron-donating and electron-withdrawing groups, obtaining uniformly moderate yields in all cases (3la-3oa).

We further explore the performance of different ethers using the optimized procedure (Scheme 4). 1,4-Dioxane (2b) and THP (2c) were also suitable for this protocol, obtaining products $3 \mathbf{a b}$ and 3ac in moderate yields after purification, as well as compound 4a as the byproduct. With THP, minor amounts of regioisomers were formed (see the ESI $\dagger$ for GC-MS of isomers), complicating the isolation of 3ac in a pure form. Acyclic ethers such as $\mathrm{i}-\mathrm{Pr}_{2} \mathrm{O}(2 d), n-\mathrm{Bu}_{2} \mathrm{O}$ (2e) and $t$-BuOMe $(2 g)$ afforded the corresponding products in good to excellent

yields, with linear $n$ - $\mathrm{Bu}_{2} \mathrm{O}$ providing the best yield. 2 -MeTHF (2f) was also examined, affording the more substituted compound 3af as the major product and regioisomer 3'af as an inseparable trans/cis mixture. Surprisingly, when $\mathrm{Bn}_{2} \mathrm{O}$ (2h) was examined, the expected product (3ah) was obtained in only $17 \%$ yield and the addition of a benzyl radical took place preferentially ( $\mathbf{3}^{\prime} \mathbf{a h}$ ). It seems reasonable that after H -abstraction from $\mathrm{Bn}_{2} \mathrm{O}$, a $\beta$-fragmentation gives rise to the benzyl radical, which is finally added to 1a. The addition of phthalan (2i) was also possible, but compound 3ai was obtained in lower yield. Importantly, acetals $2 \mathbf{j}$ and $2 \mathbf{k}$ led, respectively, to products 3aj and 3ak in synthetically useful yields. These compounds could be easily hydrolyzed to obtain the corresponding 6 -formylphenanthridine and the acetal moiety has the potential to be transformed into other functionalities. ${ }^{19}$

## Investigation of the reaction mechanism

To gain insight into the reaction mechanism we performed some experiments. As shown in Scheme 5a, the use of TEMPO as a radical scavenger in our model reaction, under standard conditions, completely inhibited the formation of 3aa and the coupling product 5 was detected by MS. Since compounds $\mathbf{4}$ are consistent byproducts of the radical cyclization studied here, we were intrigued about their formation and we have not found any experimental evidence of this in the literature. ${ }^{20}$

When the reaction was conducted using $\mathrm{D}_{2} \mathrm{O}$ and $\mathrm{D}_{8}$-THF (Scheme 5b), the expected product $\mathbf{D}_{7}-3 \mathbf{a a}$ was obtained,

(c) Intermolecular KIE :

(d) Competition experiments:

Scheme 5 Mechanistic investigations.
accompanied by phenanthridine $\mathbf{4 a}$. Importantly, the byproduct of this reaction is not deuterated, indicating that neither THF nor $\mathrm{H}_{2} \mathrm{O}$ is the source of hydrogen for the formation of this phenanthridine. We also studied the intermolecular kinetic isotopic effect (KIE) by competition experiments of equimolar amounts of THF and $\mathrm{D}_{8}$-THF with 1a at the initial stage of the reaction (Scheme 5c). The large KIE obtained $\left(k_{\mathrm{H}} / k_{\mathrm{D}}=3.16\right)$ suggests that the cleavage of the $\mathrm{C}\left(\mathrm{sp}^{3}\right)-\mathrm{H}$ bond is involved in the rate determining step of this reaction. In addition, we also performed competition experiments at the initial state of the reaction, using equimolar quantities of $\mathbf{1 a}$ and 2-isocyanobiphenyls substituted in position $4^{\prime}$ by methyl or fluoro groups. The results shown in Scheme 4d suggested that electron-withdrawing substituents in the upper aromatic ring accelerate the reaction. Since this class of group stabilizes the LUMO of the upper aromatic ring, this result is also consistent with a radical cyclization pathway. ${ }^{21}$

An important feature of this protocol is the crucial role of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and $\mathrm{H}_{2} \mathrm{O}$ in a successful transformation (Table 1, entries 6 and 9). Since the seminal contribution of Studer and Curran, ${ }^{22}$ several known reactions have been recognized as "base promoted homolytic substitutions" (BHAS) and many new transformations have been developed with this concept. ${ }^{11}$ Based on literature precedents and our own results, we believe that this reaction is an example of BHAS. A possible reaction mechanism is depicted in Scheme 6. Firstly, homolysis of TBPB takes place upon heating. From the two generated radicals, it is reported that $t$-BuO* abstracts a hydrogen atom from THF faster than $B z^{\circ}$-to generate the $\alpha$-furanyl radical. ${ }^{23}$ Addition of this intermediate to isonitrile 1a, followed by intramolecular addition to the upper aromatic ring, is well documented in a number of examples. ${ }^{11}$ DFT studies performed by the Studer group indicate that cyclohexadienyl radicals, such as $\mathbf{I}$, are extremely strong acids $\left(\mathrm{p} K_{\mathrm{a}} \sim-15\right.$ in $\left.\mathrm{H}_{2} \mathrm{O}\right) .{ }^{24}$ Therefore, this radical intermediate can be deprotonated under mild basic aqueous conditions (e.g. $\mathrm{K}_{2} \mathrm{CO}_{3}$ in $\mathrm{H}_{2} \mathrm{O}$ ) to generate a radical anion II. This species is a potent reductant

Scheme 6 Plausible mechanism.
that can easily transfer an electron to radical $\mathrm{Bz}^{*}$ or to oxidant TBPB, while generating product 3aa. In addition, intermediate I can transfer a hydrogen atom to 1a, which after a similar BHAS process leads to the formation of byproduct 4a. This explanation is consistent with our observation that neither THF nor $\mathrm{H}_{2} \mathrm{O}$ was the hydrogen source of $4 \mathrm{a} .{ }^{25}$

## Conclusions

In conclusion, we have demonstrated that TBPB can be used under mildly basic aqueous conditions to promote the radical addition of a range of ethers to 2 -isocyanobiaryls followed by cyclization. Mechanistic investigations suggest that this transformation is an example of BHAS and a plausible explanation is provided for the formation of byproduct 4. Some salient features of the developed methodology are: (a) neither transition metals nor any expensive additives are needed; (b) the wastes generated are harmless inorganic salts and can be easily removed by aqueous workup; (c) the reaction medium is constituted by the reactant ethers and water.

## Experimental section

## General remarks

All starting isonitriles were prepared according to a reported method. ${ }^{10 b}$ TLC was performed on silica gel $60 \mathrm{~F}_{254}$, using aluminium plates and visualized by exposure to ultraviolet light. Flash chromatography was carried out on hand-packed columns of silica gel 60 (230-400 mesh). Infrared (IR) spectra were recorded with a spectrophotometer equipped with an ATR component; wavenumbers are given in $\mathrm{cm}^{-1}$. LRMS were obtained using a mass spectrometer coupled with a gas chromatographer (GC); the mobile phase was helium ( 2 mL $\min ^{-1}$ ); HP-1 column of 12 m was used; temperature program starts at $80^{\circ} \mathrm{C}$ for 3 min , then up to $270{ }^{\circ} \mathrm{C}$ at a rate of $20^{\circ} \mathrm{C}$ $\min ^{-1}$, and 17.5 min at $270{ }^{\circ} \mathrm{C}$. HRMS analyses were carried out using Electron Impact (EI) mode at 70 eV by Q-TOF. ${ }^{1} \mathrm{H}$ NMR spectra were recorded at 300 or 400 MHz for ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and 75 or 100 MHz for ${ }^{13} \mathrm{C}-\mathrm{NMR}$, using $\mathrm{CDCl}_{3}$ as the solvent and TMS as an internal standard ( 0.00 ppm ). The data are being reported as $(\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{m}=$ multiplet or unresolved, br $\mathrm{s}=$ broad signal, coupling constant(s) in Hz , integration). ${ }^{13} \mathrm{C}$-NMR spectra were recorded with ${ }^{1} \mathrm{H}$-decoupling at 100 MHz and referenced to $\mathrm{CDCl}_{3}$ at 77.16 ppm . DEPT-135 experiments were performed to assign $\mathrm{CH}, \mathrm{CH}_{2}$ and $\mathrm{CH}_{3}$.

## General procedure for the synthesis of compounds 3

Into a pressure tube were added $\mathrm{K}_{2} \mathrm{CO}_{3}(103 \mathrm{mg}, 0.75 \mathrm{mmol})$ and $\mathrm{H}_{2} \mathrm{O}(0.82 \mathrm{~mL})$. Then, to it were added sequentially the 2-isocyanobiaryl derivative $1(0.50 \mathrm{mmol})$, ether $2(2.5 \mathrm{~mL})$ and tert-butyl peroxibenzoate (TBPB) ( $213 \mu \mathrm{~L}, 1.10 \mathrm{mmol}$ ). The reaction mixture was stirred under an Ar atmosphere for $12-14 \mathrm{~h}$ at $110{ }^{\circ} \mathrm{C}$ (sand bath temperature). Upon full conver-
sion of the isonitrile (TLC or GC), a saturated solution of $\mathrm{NaHCO}_{3}(5 \mathrm{~mL})$ and EtOAc $(10 \mathrm{~mL})$ was added to the reaction mixture. After phase separation, the aqueous phase was extracted with EtOAc $(3 \times 15 \mathrm{~mL})$ and the combined organic layers were washed with brine ( 5 mL ), dried over $\mathrm{MgSO}_{4}$ and concentrated under reduced pressure. The residue was purified by flash column chromatography on silica gel to give the desired product.
6-(Tetrahydrofuran-2-yl)phenanthridine (3aa). ${ }^{13 c}$ Following the general procedure, compound 3aa was obtained after column chromatography (hexane/EtOAc 9:1) as a yellow pale solid ( $91 \mathrm{mg}, 0.36 \mathrm{mmol}, 73 \%$ ): $R_{\mathrm{f}} 0.23$ ( $95: 5$ hexane/EtOAc); ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 8.63(\mathrm{dd}, J=8.2,1.3 \mathrm{~Hz}, 1 \mathrm{H}), 8.55$ (dd, $J=8.0,1.5 \mathrm{~Hz}, 1 \mathrm{H}), 8.45$ (dd, $J=8.7,1.0 \mathrm{~Hz}, 1 \mathrm{H}), 8.19$ (dd, $J=7.9,1.6 \mathrm{~Hz}, 1 \mathrm{H}$ ), 7.83 (ddd, $J=8.3,7.0,1.3 \mathrm{~Hz}, 1 \mathrm{H}$ ), $7.75-7.61(\mathrm{~m}, 3 \mathrm{H}), 5.78(\mathrm{t}, J=6.9 \mathrm{~Hz}, 1 \mathrm{H}), 4.26-4.15(\mathrm{~m}, 1 \mathrm{H})$, 4.13-4.01 (m, 1H), 2.82-2.65 (m, 1H), 2.50-2.35 (m, 1H), 2.30-2.03 (m, 2H) ppm; ${ }^{13} \mathrm{C}-\mathrm{NMR}\left(101 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 159.4$ (C), 143.4 (C), 133.4 (C), 130.6 (CH), 130.4 (CH), 128.6 (CH), 127.3 (CH), 127.0 (CH), 126.6 (CH), 124.9 (C), 124.2 (C), 122.5 $(\mathrm{CH}), 122.0(\mathrm{CH}), 79.7(\mathrm{CH}), 69.1\left(\mathrm{CH}_{2}\right), 30.1\left(\mathrm{CH}_{2}\right), 26.1\left(\mathrm{CH}_{2}\right)$ ppm; IR $\nu 3073,2981,2881,1583,1444,1300,1057,727 \mathrm{~cm}^{-1}$; LRMS (EI) $m / z(\%)=249\left(\mathrm{M}^{+}, 5\right), 220(15), 206(100), 193(48)$, 178 (15).
8-Methyl-6-(tetrahydrofuran-2-yl)phenanthridine (3ba). 17 A similar result was observed by the group of Ji (ref. 13a) with 1,4-dioxane and TBPB as the oxidant.
18 This regiochemistry was observed by the group of Chen, using 1,4-dioxane and BPO as the oxidant. A plausible explanation is given in ref. $13 b$.

19 For selected examples, see: (a) T. Akindele, Y. Yamamoto, M. Maekawa, H. Umeki, K.-I. Yamada and K. Tomioka, Org. Lett., 2006, 8, 5729; (b) I. Hayakawa, H. Watanabe and H. Kigoshi, Tetrahedron, 2008, 64, 5873.

20 It is worth noting that compound $\mathbf{4 a}$ is significantly formed with TBPB in the absence of base (ref. $13 a$ and checked by us in Table 1, entry 7); or with BPO in neutral media (ref. $13 b$ and checked by us in Table 1, entry 1).

25 An intramolecular electrophilic aromatic substitution might also be considered as a plausible pathway for the formation of byproduct 4a. Due to the extremely high acidity of cyclohexadienyl radical $\mathbf{I}$, a proton transfer to the isonitrile moiety of $\mathbf{1 a}$ would form a cationic intermediate that could undergo Friedel-Crafts-type cyclization to give 4a.
