# Comment on "A quantitative definition of hypervalency" by M. C. Durrant, *Chem. Sci.*, 2015, 6, 6614

Richard D. Harcourt<sup>\*a</sup> and Thomas M. Klapötke<sup>b</sup>

Consideration is given to (electronically) hypervalent increased-valence structures, which possess 2c–1e bonds, fractional 2c–2e bonds, and usually normal 2c–2e bonds. For singlet-spin electron-rich systems, increased-valence structures, with Heitler–London 2c–2e bond wavefunctions, are equivalent to resonance between non-hypervalent Kekulé and Dewar (or singlet diradical) type Lewis structures. Dewar structures are not considered in the *Chem. Sci.* 2015, 6, 6614 Edge article on hypervalency. Using one-electron delocalizations from lone-pair atomic orbitals into separate bonding molecular orbitals, increased-valence structures for  $\text{PCl}_5$ ,  $\text{O}_3$ ,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$ ,  $\text{N}_2\text{O}_4$  and  $\text{S}_\text{N}2$  reactions are derived from the Edge-article's Kekulé-type Lewis structures, and compared with the Edge article's hypervalent structures with 2c–2e bonds. It is also shown that Durrant's method to determine the  $\gamma$  parameter for XAY-type systems that possess a symmetrical 3c–4e bonding unit is related to the A-atom charge density.

## Introduction

Durrant<sup>1</sup> has provided a quantitative definition of hypervalency *via* reference to atomic charges, which were obtained either from experimental or from theoretical electron densities using Bader's quantum theory of atoms in molecules (QTAIM) methodology.<sup>3</sup> Without calculation it was not usually possible to conclude whether a given molecule was hypervalent. For example, the hypercoordinate molecules  $\text{ClLi}_6$  and  $\text{SiH}_6^{2-}$  were calculated<sup>1</sup> to be hypervalent and non-hypervalent, respectively.<sup>4</sup>

For this comment on hypervalence (primarily for electron-rich molecules), we use and discuss types of hypervalent VB structures that were not considered in ref. 1, and which, since 1968,<sup>8,9</sup> have been designated as "increased-valence" structures without expansion of valence shells. They involve 2-centre, 1-electron (2c–1e) bonds and fractional 2c–2e bonds (with bond-numbers less than unity, and represented by thin bond lines),<sup>6,8,9</sup> and usually non-fractional 2c–2e bonds.

In Schemes 1, 2 and 4–6, increased-valence structures for  $\text{PCl}_5$ ,  $\text{O}_3$ ,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$  and  $\text{N}_2\text{O}_4$  are generated from Lewis octet VB structures and compared with the non-octet hypervalent VB structures displayed in ref. 1, namely structures 1a, 2c, 4c, 5c and 6c here. Brief consideration is also given to increased-valence structures for  $\text{S}_\text{N}2$  reactions.

For illustrative purposes, in the Appendix we show that Durrant's method to determine the  $\gamma$  parameter of ref. 1 for XAY-type systems with a symmetrical 3c–4e bonding unit is related to the A-atom charge density obtained from a 3c–4e molecular orbital (MO) configuration. Consideration is also given to the A-atom valence.

## Increased-valence structures and hypervalence

For  $\text{PCl}_5$ ,  $\text{O}_3$ ,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$  and  $\text{N}_2\text{O}_4$ , Durrant<sup>1</sup> has displayed two types of Lewis VB structures that involve non-fractional (2c–2e)

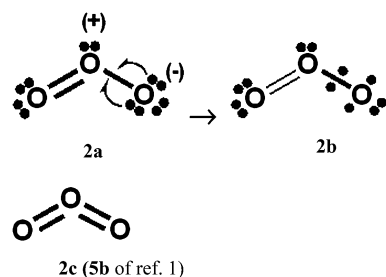

**Scheme 1** Hypercoordinate  $\text{PCl}_5$  valence-bond (VB) structures. Here and in Schemes 2–6, (non-variationally best) atomic formal charges for increased-valence structures are assigned on the assumption that bonding electrons are shared equally by pairs of adjacent atoms,<sup>9</sup> and mirror-image structures are not displayed. Of course the extent of delocalization differs for non-equivalent 3c, 4e bonding units.

<sup>b</sup>Department of Chemistry, Ludwig-Maximilian University of Munich, Butenandstr. 5-13(D), D-81377 Munich, Germany

Scheme 2  $\text{O}_3$  VB structures.

bonds between pairs of adjacent atoms, namely familiar, non-hypervalent octet Kekulé type structures **1c**, **2a**, **3a**, **4a**, **5a** and **6a**, and the hypervalent structures **1a**, **2c**, **4c**, **5c**, and **6c** that violate the octet rule. For electron-rich hypercoordinate molecules, such as  $\text{PCl}_5$  (cf. Scheme 1 of ref. 1 and Scheme 1 here) and for the electron-rich non-hypercoordinate molecules and ions  $\text{O}_3$ ,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$  and  $\text{N}_2\text{O}_4$ , 2c–2e bonds are the only types of bonds that are present in both types of Lewis VB structures.

Dewar/singlet diradical types of Lewis VB structures, such as **1b** and **3b–3d**, were not considered in ref. 1. In ref. 6, it is indicated that hypervalency for electron-rich systems arises when Dewar/type structures participate in resonance with the Kekulé type structures.

When relevant atomic orbitals (AOs) overlap, Lewis-type VB structures for electron-rich species can be stabilized *via* 1-electron delocalizations from separate lone-pair AOs into 2-centre bonding MOs or bond orbitals (BOs), as is shown, for example, in structures **1c** for  $\text{PCl}_5$  in Scheme 1, and **2a**, **4a**, **5a** and **6a** for  $\text{O}_3$ ,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$  and  $\text{N}_2\text{O}_4$  in Schemes 2 and 4–6. The resulting VB structures, **1d**, **2b**, **4b**, **5b** and **6b** possess (thin-bond line) fractional 2c–2e bonds and 2c–1e bonds, as well as normal 2c–2e bonds.

By inspection, one can see that more electrons participate in bonding in VB structures **1d**, **2b**, **4b**, **5b** and **6b** than does occur in the Lewis Kekulé structures **1c**, **2a**, **4a**, **5a** and **6a**. Therefore **1d**, **2b**, **4b**, **5b** and **6b** are examples of “increased-valence” structures<sup>6,8,9</sup> without expansion of the valence shell. Because relative to the octet Lewis structures, increased-valence structures involve additional electrons in both nearest-neighbour and non-neighbour bonding, increased-valence structures are hypervalent relative to the Lewis structures.<sup>6,8,9</sup>

### Some properties of increased-valence structures

With Heitler–London AO type wavefunctions for 2c–2e bonds – for example  $a(1)b(2) + b(1)a(2)$  for the 2c–2e A–B bond – increased-valence structures for electron-rich molecules summarize resonance between two types of Lewis structures, namely the familiar, standard/Kekulé type Lewis octet structures, and “long-bond”/formal bond/singlet diradical/Dewar type Lewis (octet) structures. As indicated already, the latter type of Lewis VB structure is not considered in ref. 1. For the  $\text{O}_3$  increased-valence structure **2b**, these two types of Lewis octet structures (namely structure **3a** and structures **3b–3d**) are displayed in Scheme 3. None of them is hypervalent, but resonance

between them generates hypervalence for the resulting increased-valence structure.

The  $\text{PCl}_5$  and  $\text{O}_3$  Dewar structures **1b**, **3b** and **3d** do not carry atomic formal charges, and **1b** and **3d** in particular were not considered by Durrant.

For an increased-valence structure that does not involve a valence shell expansion to provide an additional AO for bonding, none of the component Lewis structures violates the octet rule, but resonance between them to generate the increased-valence structure leads to (an apparent) violation of the octet rule.<sup>6,8,9</sup>

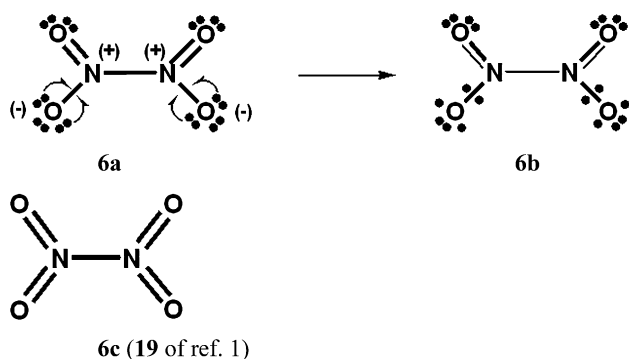

### Increased-valence structures for $\text{SO}_4^{2-}$ , $\text{NO}_3^-$ and $\text{N}_2\text{O}_4$

In Schemes 4–6, we have generated increased-valence structures for  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$  and  $\text{N}_2\text{O}_4$  from familiar octet Kekulé type Lewis structures *via* 2c–1e delocalizations of oxygen  $\text{O}^-$  electrons. In these figures, the hypervalent VB structures with only 2c–2e bonds displayed in ref. 1 are also displayed. We suggest that the

Scheme 3 Component Kekulé and Dewar/singlet diradical Lewis structures for increased-valence structure **2b** of Scheme 2.Scheme 4  $\text{SO}_4^{2-}$ . As well as structure **4b**, another type of increased-valence structure can be constructed with four fractional 2c–2e bonds + four 2c–1e bonds and oxygen atom formal charges of  $-1/2$ .

**Scheme 5**  $\text{NO}_3^-$ . As well as 5b, another type of increased-valence structure can be constructed, with two fractional 2c–2e bonds and two oxygen atoms with formal charges of  $-1/2$ .

**Scheme 6**  $\text{N}_2\text{O}_4$  with  $D_{2h}$  symmetry. The 16 component Kekulé and Dewar Lewis structures are displayed in ref. 9a and b, as well as an increased-valence structure for an ONONO<sub>2</sub> isomer. There are two “cis” type structures for each of 6a and 6b, and two “trans” type structures.

increased-valence structures with 1-electron bonds and fractional 2c–2e bonds provide better insight into the possible origin of some molecular properties than do the hypervalent VB structures of ref. 1. For example:

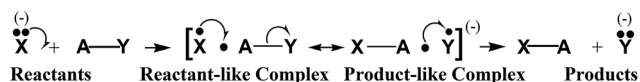

(a) The fractional N–N 2c–2e bond in the increased-valence structure 6b for  $\text{N}_2\text{O}_4$  is in accord with the presence of a long, weak N–N single bond.<sup>9</sup>

(b) The results of VB calculations for  $\text{O}_3$  and related 1,3-dipolar systems from numerous laboratories – see for example ref. 7d and e and 10 and references therein – indicate that their ground-states possess substantial singlet-diradical character. It arises primarily from the contribution of the Lewis structure 3d of Scheme 3 to the ground-state Lewis structure resonance scheme. In contrast to structure 2c (*i.e.* structure 5b of ref. 1), increased-valence structure 2b of Scheme 2 reflects the diradical character.

### $\text{S}_{\text{N}}2$ reactions

With Coulson–Fischer<sup>11</sup> type BOs ( $a + k_1b$ ) and ( $b + k_2a$ ) replacing the  $a$  and  $b$  AOs of the Heitler–London wavefunction for

a 2c–2e bond, the course of an  $\text{S}_{\text{N}}2$  reaction,  $\text{X}^- + \text{AY} \rightarrow \text{XA} + \text{Y}^-$  has been formulated<sup>12</sup> as

For it, the increased-valence structures for the  $(\text{XAY})^-$  reactant-like and product-like complexes, each with an additional bonding electron relative to the  $\text{AY}$  reactant and  $\text{XA}$  product, are both hypercoordinate and hypervalent relative to the VB structures for the latter species.

### Further comments and conclusion

When 2-centre Coulson–Fischer type BOs, such as the  $a + k_1b$  and  $b + k_2a$  above, are used to accommodate the electrons that form the fractional 2c, 2e bonds in the increased-valence structures, allowance can be made for polarization of these bonds.

In ref. 13, the wavefunctions for 3c–4e VB structures of the types  $\text{X}-\text{A}-\text{Y}$  (as would occur in the Durrant structures 2c, 5c and 6c for  $\text{O}_3$ ,  $\text{NO}_3^-$  and  $\text{N}_2\text{O}_4$  if expansion of the valence shell does not occur) and  $\bullet\text{X} \bullet \text{A} \bullet \text{Y} \bullet$ , and the Rundle-Hach<sup>14</sup>–Pimentel<sup>15</sup> 3c–4e MO configuration have been shown to be special cases of wavefunctions for resonance between the increased-valence structures  $\bullet\text{X} \bullet \text{A}-\text{Y}$  and  $\text{X}-\text{A} \bullet \text{Y} \bullet$ , with 2-centre Coulson–Fischer orbitals, and one variational parameter.<sup>16</sup>

Increased-valence structures can also be constructed for: (a) systems that involve 3c–3e bonding units,<sup>17</sup> with non-reactant and non-product ionic structures replacing the singlet-diradical structures of electron-rich systems, and (b) diatomic molecules.<sup>18</sup>

Regardless of the method used to construct the wave-functions for increased-valence structures, because they involve the participation of more electrons in bonding than do the Kekulé-type Lewis structures from which they are derived, increased-valence structures are hypervalent relative to these Lewis structures. As indicated above, for electron-rich systems, this is due to the inclusion of singlet diradical structures in the Lewis structure resonance scheme. Also, increased-valence structures involve at least one Pauling three-electron bond as a diatomic component.<sup>9</sup>

## Appendix: valence electron equivalent parameter $\gamma(\text{A})$ and atomic valencies

In ref. 1, the valence electron equivalent parameter  $\gamma(\text{A})$  for atom  $\text{A}$  is used to determine whether a molecule exhibits hypervalence.<sup>19</sup> Here for the linear, symmetrical, triatomic systems of Table 1, each with one 3c–4e bonding unit, we shall show that the Durrant method<sup>1</sup> to construct  $\gamma(\text{A})$  is equivalent to a method that uses a 3c–4e MO configuration with AO overlap integrals omitted.

### MO wavefunction

As the wavefunction for the 3c–4e electrons, we shall use the Hach–Rundle–Pimentel MO configuration<sup>14,15</sup> of eqn (1).

Table 1  $\gamma(\text{A})$  and A-atom valencies

Molecule	A-atom charge <sup>1</sup>	$k^2$	$\gamma(\text{A})$	A-Atom valence
$\text{F}_3^-$	-0.056	2.13 <sub>7</sub>	8.11	1.35
$\text{ClF}_2^-$	+0.291	1.09 <sub>8</sub>	7.42	1.11
$\text{Cl}_3^-$	-0.019	2.07 <sub>7</sub>	8.04	1.34
$\text{BrCl}_2^-$	+0.108	1.16 <sub>0</sub>	7.78	1.27
$\text{ICl}_2^-$	+0.263	1.16 <sub>7</sub>	7.47	1.14
$\text{XeF}_2$	+1.230	1.25 <sub>2</sub>	7.54	1.17
$\text{KrF}_2$	+1.003	1.98 <sub>8</sub>	7.99	1.06
$\text{XeCl}_2$	+0.763	3.24 <sub>2</sub>	8.47	1.37

$$|\psi_1^\alpha \psi_1^\beta \psi_2^\alpha \psi_2^\beta| \propto |(2x + ka)^\alpha (2x + ka)^\beta (2y + ka)^\alpha (2y + ka)^\beta| \quad (1)$$

The  $x$ ,  $a$  and  $y$  are the overlapping AOs on the three atomic centres, and  $\psi_1 = x + ka + y$  and  $\psi_2 = x - y$  are the bonding and non-bonding MOs that can be constructed from them.<sup>14,15</sup>

The right-hand side of eqn (1) gives the valence-bond structure<sup>21</sup>  $(\text{X}-\text{A}-\text{Y})^q$ , with fractional 2c-2e bonds that arise from double-occupation of two non-orthogonal BOs, and  $q = -1$  or 0.

To determine the value for  $k$ , we equate the charge  $Q_{\text{A}}$  of ref. 1 for atom A to  $X_{\text{A}} - 2k^2/(k^2 + 2)$ . The  $X_{\text{A}}$  is the core charge of atom A when the 3c-4e electrons are removed, and  $2k^2/(k^2 + 2) = P_{\text{aa}}$  is the A-atom charge density that arises from the 3c-4e bonding. For the neutral species and anions of Table 1,  $X_{\text{A}} = 2$  and 1, respectively.

### Durrant's method<sup>1</sup> to construct $\gamma(\text{A})$

To construct the  $\gamma(\text{A})$  parameter for the systems considered in Table 1, initially we follow Durrant's methodology,<sup>1</sup> as described in ref. 1 for CO, and for  $\text{SCl}_4$  in the ESI for ref. 1. We use the expanded valence-shell (hypervalent) covalent structure  $\text{X}-\text{A}^{(q)}-\text{Y}$  (with two non-fractional 2c-2e bonds) and the ionic structure  $\text{X}^{(-)}\text{A}^{(q+2)}\text{Y}^{(-)}$  (with  $q = X_{\text{A}} - 2$ ).

These structures are weighted according to the value of  $q = X_{\text{A}} - 2$  so that the QTAIM charge  $Q_{\text{A}}$  of ref. 1 is reproduced via eqn (2)

$$xq + (1 - x)(q + 2) = Q_{\text{A}} \quad (2)$$

to give  $x = (X_{\text{A}} - Q_{\text{A}})/2$ .

The  $\gamma(\text{A})$  is then calculated from eqn (4) via eqn (3),

$$\gamma(\text{A}) = 10x + 6(1 - x) \quad (3)$$

$$= 6 + 2(X_{\text{A}} - Q_{\text{A}}) \quad (4)$$

in which 10 and 6 are the number of A-atom electrons associated with the covalent and ionic structures.

### MO method to construct $\gamma(\text{A})$

Alternatively we can use the 3c-4e MO configuration of eqn (1), and a  $k$ -dependent probability density function ( $P(k)$ ) for the 3c-4e bonding unit. If we choose  $P(k) = 4k^2/(k^2 + 2) \equiv 2P_{\text{aa}}$ , with  $Q_{\text{A}} = X_{\text{A}} - 2k^2/(k^2 + 2)$ , the resulting  $\gamma(\text{A})$  parameter is given by eqn (6) via eqn (5).

$$\gamma(\text{A}) = 6 + 4k^2/(k^2 + 2) \quad (5)$$

$$= 6 + 2(X_{\text{A}} - Q_{\text{A}}) \quad (6)$$

Therefore eqn (3) is identical to eqn (5), thereby showing that the Durrant methodology to determine  $\gamma(\text{A})$  for a symmetric 3c-4e bonding unit corresponds to using a contribution by the A-atom's charge density to a MO formulation of 3c-4e bonding.

Three of the calculated values for  $\gamma(\text{A})$  reported in Table 1 are greater than 8, which indicates hypervalency<sup>1</sup> for the associated species. However of course different numerical values and conclusions would be obtained with different types of 3c-4e wavefunctions and  $P(k)$  functions.

### A-Atom valence

In ref. 22, with AO overlap integrals omitted, it is deduced that the A-atom valence ( $V_{\text{A}}$ ) for the MO configuration of eqn (1) is given by eqn (7),

$$V_{\text{A}} = V_{\text{ax}} + V_{\text{ay}} = 16k^2/\{(k^2 + 4)(k^2 + 2)\} \quad (7)$$

with a maximum value of 1.3726 when  $k^2 = 2\sqrt{2}$ .

In Table 1, the MO estimates of the A atom valence for each species exceeds unity, and therefore its A atom is hypervalent. However, regardless of the values of the A-atom valence and the  $\gamma(\text{A})$ , because of the presence of 2c-1e bonds in addition to the 2c-2e bonds, more electrons participate in nearest-neighbour and non-neighbour bonding<sup>6,8,9</sup> for each of the increased-valence structures than does occur in any of their component Lewis structures. Therefore all increased-valence structures are electronically hypervalent.

## Note added in proof

For  $\text{PCl}_5$ , an increased-valence analogue of structure **1a** is obtained via the delocalization of two electrons from the  $\text{Cl}^-$  of the Kekulé structure **1c** rather than one (as in structure **1c**), to give two 1-electron P-Cl bonds, a fractional equatorial 2c-2e P-Cl bond as well as the fractional axial 2c-2e P-Cl bond of structure **1d**.

## Acknowledgements

We thank Dr Margaret-Jane Crawford for drawing the valence bond structures. We also thank and appreciate the Reply by Durrant to our Comment.
