Exploring the solid state and solution structural chemistry of the utility amide potassium hexamethyldisilazide (KHMDS)†

Ana I. Ojeda-Amador, Antonio J. Martínez-Martínez, Gemma M. Robertson, Stuart D. Robertson, Alan R. Kennedy and Charles T. O’Hara

The structural chemistry of eleven donor complexes of the important Brønsted base potassium 1,1,1,3,3,3-hexamethyldisilazide (KHMDS) has been studied. Depending on the donor, each complex adopted one of five general structural motifs. Specifically, in this study the donors employed were toluene (to give polymeric 1 and dimeric 2), THF (polymeric 3), N,N,N,N′-tetramethylthelyenediamine (TMEDA) (dimeric 4), (R,R)-N,N,N,N′-tetramethyl-1,2-diaminocyclohexane [(R,R)-TMEDA] (dimeric 5), 12-crown-4 (dimeric 6), N,N,N,N′-tetramethylaminoethoxy ether (TMDAE) (tetraneuric dimeric 8) and monomeric 10, N,N,N′,N″-pentamethyldiethylenetriamine (PMDEA) (tetraneuric dimeric 7), tris[2-dimethyl (amino)ethyl]amine (Me6TREN) (tetraneuric dimeric 9) and tris[2-(2-methoxyethoxy)ethyl]amine (TMEEA) (monomeric 11). The complexes were also studied in solution by 1H and 13C NMR spectroscopy as well as DOSY NMR spectroscopy.

Introduction

Alkali metal complexes of 1,1,1,3,3,3-hexamethyldisilazide (HMDS) are commonly employed reagents in synthesis due to their non-nucleophilic but Brønsted basic nature.1,2 In comparison with related alkali metal secondary amide reagents such as diisopropylamide (DA) and 2,2,6,6-tetramethylpiperididide (TMP) salts, HMDS is weakly basic due to its inherent α-silyl stabilisation. The pK of LiHMDS in tetrahydrofuran (THF) solution is 24 whereas for LiDA and LiTMP are 35 and 36 respectively.3 Additionally, the absence of β-hydrogen atoms prevents β-hydride elimination, and their lipophilic character makes alkali metal derivatives of the HMDS group special candidates for many homogeneous reactions. Since lithium, sodium and potassium HMDS reagents are commercially available, they have become prominent transfer reagents for the synthesis of s-block metal,4 transition metal,5-7 lanthaneide8 and actinide9,10 HMDS complexes via salt metathesis. In synthesis, they are used in a wide variety of chemical transformations ranging from drug synthesis to polymer production, such as in the formation of kinetic enolate anions,11-13 alkylation,14 arylation,15 isomerisations,16 polymerizations,17 ring closing reactions and Wittig reactions,18,19 and also, in the deprotonative metallation of acidic C–H bonds, like cyclopentadiene, indene and fluorene.20-22 Most recently, several organic transformations have been reported which use alkali metal HMDS salt complexes in combination with a Lewis basic donor molecule to induce catalysis. In particular, KHMDS has attracted special attention due to its slightly increased Brønsted basic character when compared with its lighter lithium or sodium congeners,3 but also because of its relatively low toxicity23 and as such can be used in medical-related fields which are incompatible with conventional transition metal-catalysed approaches. In this context, the seminal work by Kobayashi24 has recently shown that KHMDS in combination with chiral macrocyclic crown ethers (as Lewis basic donor molecules) acts as an effective catalytic system for the carbon–carbon bond-forming reaction of alkyl nitriles and 1,5-dicarbonyl compounds with excellent diastereo- and enantioselectivities.25,26 Wilhelm reported that KHMDS exhibits catalytic activity in the presence of THF, at temperatures as low as −78 °C, for the [2 + 2] cycloaddition of ketenes with imines and aldehydes to produce biologically important β-lactam and β-lactone feedstocks.27 Zhang has shown that N-alkyl substituted carbamates undergo 5-exo-dig-cyclization to afford the corresponding functionalised oxazolidinone derivatives catalysed by KHMDS and 18-crown-6 in toluene solution.28 Panda and Carpentier have illustrated the

use of KHMDS as a pre-catalyst with a higher activity than the lithium and sodium salts for cross-dehydrocoupling of boranes and silanes, respectively, with a high degree of conversion and chemoselectivity. The benefit of using potassium over lithium and sodium derivatives in synthesis could also be exemplified in the tert-butoxide congener of KHMDS (KO\textsubscript{t}Bu). For instance, Shi\textsuperscript{31} reported the use of KO\textsubscript{t}Bu in combination with the chelating Lewis base donor 1,10-phenanthroline as a transition metal-free catalytic system for constructing biaryl systems via radical cross-coupling between inert aromatic C–H bonds and aryl iodides or bromides. Murphy and Tuttle\textsuperscript{32} have studied in detail the mechanism of these transformations concluding that the greater basicity of KO\textsubscript{t}Bu over its sodium and lithium counterparts is a crucial factor in allowing access to these electron transfer reactions.

Since KHMDS is a widely used Brønsted base in synthesis and has recently shown excellent catalytic potential in THF or toluene solutions in the presence of Lewis basic donor molecules, it is important to understand the structural chemistry which is at play with these reagents in these solvents. The structural chemistry of LiHMDS and NaHMDS has been well studied; however, it is perhaps surprising that for the commercially available KHMDS (as toluene and THF solutions) it remains largely unexplored. To date, the solvent-free dimeric [(KH\textsubscript{2}MD)\textsubscript{2}],\textsuperscript{33} dimeric toluene-solvated [(KH\textsubscript{2}MD)\textsubscript{2}(toluene)]\textsubscript{2},\textsuperscript{34} dimeric ammonia-solvated [(KH\textsubscript{2}MD)\textsubscript{2}(NH\textsubscript{3})\textsubscript{2}]\textsuperscript{35} complexes and the monomeric species [KH\textsubscript{2}MD](donor) (donor = 1,4-dioxane\textsuperscript{16} and 18-crown-6\textsuperscript{37,38}) have been structurally characterized (Fig. 1a–d) alongside two examples of N-heterocyclic carbene (NHC) dimeric adducts of KHMDS, namely [(KH\textsubscript{2}MC\textsubscript{2}(NHC\textsubscript{2})], where NHC are 1,3-bis(2,6-di-isopropylphenyl-imidazol-2-ylidene and 1,3-di-isopropyl-3,4,5,6-tetrahydropyrimid-2-ylidene (Fig. 1e and f).\textsuperscript{39,40} Additionally, one other related example containing a O,N-bidentate ligand derived from an ether-based backbone imidazolinium proligand [(KH\textsubscript{2}MD)\textsubscript{2}((OCMe\textsubscript{2}CH\textsubscript{2}HC)\textsubscript{2}N\textsubscript{t}Me\textsubscript{2}NPr\textsubscript{2}]\textsubscript{2} has also been reported (Fig. 1g).\textsuperscript{41}

Most of the structurally known complexes contain an archetypal dinuclear (KNHMDS)\textsubscript{2}\textsuperscript{2} core. This motif is also observed when ferrocene is added to KHMDS, resulting in the isolation of the unusual polymeric [(KH\textsubscript{2}MD)\textsubscript{2}(ferrocene)]\textsubscript{n} (Fig. 1h),\textsuperscript{42} where ferrocene n-coordinates to the potassium metal. When KHMDS is combined with alkaline earth metal amides forming mixed metallate species,\textsuperscript{43–45} it is possible to isolate inverse crown species such as hydrido-\textsuperscript{46} and oxo-variants\textsuperscript{47,48} as well as simpler bimetallic heterobimetallic amide formulations\textsuperscript{49,50} also observed when the alkaline earth metal is replaced by lanthanides.\textsuperscript{51,52} As the structural chemistry of alkali metal reagents normally dictates and influences their reactivity, it was decided to isolate and characterise, (in the solid- and solution-state) a series of solvates of KHMDS containing key solubility- and reactivity-enhancing donor molecules. These molecules include toluene, THF, N,N,N′,N′-tetramethylmethylenediamine (TMEDA), (R,R)-N,N,N′,N′-tetramethyl-1,2-diaminocyclohexane [(R,R)-TMCD], 12-crown-4, N,N,N,N′,N′-tetramethyl-diaminoethyl ether (TMDAE), N,N,N′,N′,N″,N″-penta-methyldienetriaminetramine (PMDETA), tris[2-dimethyl[amino]ethyl]amine (Me\textsubscript{2}TREN) and tris[2-(2-methoxyethyl)ethyl] amine (TMEEA).

Results and discussion

Synthetic procedures

A total of eleven new solvates of KHMDS (1–11) have been prepared and structurally characterised, both in solution and in the solid state. All synthetic protocols were optimised for obtaining high-quality crystalline samples for single crystal X-ray diffraction studies.

When toluene was employed as a donor, two distinct aggregates of KHMDS were obtained depending on the reaction conditions, a polymer [(KH\textsubscript{2}MD)\textsubscript{2}(toluene)]\textsubscript{n} 1 and a discrete dimer [(KH\textsubscript{2}MD)\textsubscript{2}(toluene)]\textsubscript{2} 2. The ‘toluene-deficient’ polymeric aggregate 1 was prepared by generating KHMDS in situ (via a salt metathesis reaction between equimolar quantities of LiHMDS and KO\textsubscript{t}Bu). This reaction mixture results in a pale-yellow suspension in n-hexane from which 1 was successfully crystallised by adding toluene at ambient temperature (2:1 mixture of n-hexane : toluene) in 38% yield (Scheme 1). However, when the reaction mixture is stored at −27 °C the 1:1 toluene : KHMDS dimeric solvate 2 was isolated in 46% yield. THF-solvate [(KH\textsubscript{2}MD)\textsubscript{2}(THF)]\textsubscript{n} 3 was obtained by adding two molar equivalents of THF to a slurry of KHMDS in n-hexane. The THF polymeric aggregate was isolated (in 34% yield) by storing the resultant solution at −27 °C (Scheme 1). To the best of our knowledge, this represents the first isolation and structural characterisation of a THF-containing derivative of KHMDS, despite this reagent-solvent combination being commonly used in synthetic chemistry. Next, two bidentate diamine donors were studied, namely TMEDA and its chiral analogue (R,R)-TMCD. To achieve homogeneity, a single molar equivalent with respect to KHMDS was required. The corresponding dimeric complexes [(KH\textsubscript{2}MD)\textsubscript{2}(TMEDA)]\textsubscript{4} 4 and
lents of Me6TREN were required in TMDAE molecules to a suspension of KHMDS in adding the corresponding tridentate donor PMDETA and solutions in both cases. Complex 0.5 : 1 donor : KHMDS molar ratios, producing homogeneous aggregates, namely \((\text{KHMDS})_2(\text{PMDETA} \cdot \text{KHMDS})_2\) structurally distinct (vide infra) \((\text{KHMDS})_2(\text{Me6TREN} \cdot \text{KHMDS})_2\) amounts of KHMDS and the crown ether molecule at \(n\)-hexane. Crystallisation at \(-\)35 °C yielded 9 in a moderate yield of 36%. Surprisingly, addition of two molar equivalents of Me6TREN did not produce full deaggregation (i.e. monomerisation) of KHMDS, but employing two molar equivalents of the N,O-containing tridentate TMDAE molecule with respect to KHMDS in \(n\)-hexane yielded the monomeric aggregate \([\text{KHMDS(TMDAE)}]_2\) 10 (Scheme 2) in good yield (62%). Finally, the N,O-containing potentially heptadentate TMEEA was added to a toluene solution of KHMDS in a 1:1 donor:KHMDS molar ratio from which \([\text{KHMDS(TMEEA)}]_2\) 11 was obtained in 69% yield upon cooling down the resulting solution to \(-27\) °C. Complexes 10 and 11 represent rare examples of monomeric KHMDS complexes (Scheme 2).

X-ray diffraction studies

As discussed earlier, depending on the crystallisation temperature, it is possible to isolate two distinct toluene solvates of KHMDS, namely polymeric \([\text{KHMDS}]_2(\text{toluene})_\infty\) 1 (Fig. 2a and b) and dimeric \([\text{KHMDS}]_2(\text{toluene})_2\) 2 (Fig. 2c). These crystallised in the triclinic space group \(\overline{P}1\) and in the monoclinic space group \(C2/c\), respectively. The asymmetric unit cell of 1 is composed of a dimeric (KHMDS)\_2\_ arrangement where one molecule of toluene is coordinated to the K metal centre in a \(\eta^6\)-manner via \(\pi\)-arene interactions \([\text{K1} \cdots \text{arene(centroid)} 3.045 \, \text{Å}]\). The structure of 1 propagates through the crystallographic \(a\)-axis via \(\pi\)-arene interactions of this toluene molecule with a second K metal centre from a neighbouring (KHMDS)\_2\ unit, ultimately forming a linear polymeric chain arrangement \([\text{K2} \cdots \text{arene(centroid)} 3.015 \, \text{Å}]\) (Fig. 2b). Complex 2 resembles the lattice parameters previously reported by Williard, although in this initial report the toluene solvent molecules were described as not coordinating to the K metal centres. 34

Here we have included our interpretation of the structural description of 2 by considering it as a four-membered \([\text{K} \cdots \text{N} \cdots \text{K} \cdots \text{N}]\) cyclodimeric unit, where each K atom is solvated by a molecule of toluene in an \(\eta^6\)-manner \([\text{K} \cdots \text{arene(centroid)} 2.967 \, \text{Å}]\). Each arene molecule binds approximately in a perpendicular array to the \(\text{K}_2\text{N}_2\) plane (87.5°) resulting in a discrete dimeric arrangement (Fig. 2c). Comparing 1 and 2, in the former the toluene molecules are disposed in a cisoid manner in the polymeric chain (Fig. 2b), whereas in 2, the toluene molecules are transoidal. This \(\eta^6\)-bonding mode of an arene to a metal is a common structural feature in heavy alkali metal organo-

metallic complexes and these K...arene(centroid) distances are similar to those found in related benzene- or toluene-solvated potassium amide complexes (range, 2.862–3.108 Å). The K,N units in both the non-centrosymmetric 1 and centrosymmetric 2 resemble those of (KHMD$_2$)$_2$ reported by Tesh and Hanusa.$^{33}$ Both K atoms are connected through bridging μ-HMD$_2$ ligands where the N atoms lie in approximately the same plane as the K metal centres [torsion angle K1–N1–K2–N2 of 1.5°, for 1; coplanar in 2]. The inclusion of an additional molecule of toluene per potassium atom, does not have a pronounced effect on the respective K–N bond distances found in 1 and 2 [K1–N 2.7726(15) and 2.7619(15) Å and K2–N 2.7506(15) and 2.7393(15) Å in 1; and 2.739(2) and 2.800(2) Å for 2, respectively; see Table 1]. These K–N bond distances are similar to those found for the solvent-free (KHMD)$_2$ [2.770(3) and 2.803(3) Å].$^{33}$ The distinct K–N bond lengths for K1 and K2 observed in 1 result in two slightly distinct N–K–N angles [N–K1–N 94.58(4) and N–K2–N 95.13(4)°], whilst the K–N–K

* K–N–K angles involving the terminal K(terminal) atoms in 7–8.
angles are identical \([K1–N1–K2 ~ 85.14(4) \text{ }^\circ \text{ and } K1–N2–K2 ~ 85.11(4)\text{ }^\circ]\). These bond angles are similar to those found in \([N1–K1–N1' ~ 94.17(7) \text{ }^\circ \text{ and } K1–N1–K1, ~ 85.83(7)\text{ }^\circ]\). In addition, each K atom exhibits long K⋯C interactions with Me groups from the HMDS ligands in 1 and 2 \([K1⋯C \text{ range } 3.237(2)–3.2951(19) \text{ and } 3.303(4)–3.402(4) \text{ }^\AA \text{ for 1 and 2, respectively}]\).

Complex 3 crystallises in the monoclinic space group \(P2_1/c\). Like most known KHMDS structures, 3 crystals as a dimeric (KHMDS)\(_2\) unit, and it contains two molecules of THF, one coordinating to each K atom (Fig. 3a). The key features and metrics resemble those found for 1 and 2, a four membered \([K–N–K–N] \text{ planar ring, two bridging } \mu\text{-HMDS ligands and for 2, two distinct K–N bond lengths [2.7442(13) \text{ and } 2.8534(12) \text{ }^\AA]\). The two THF ligands are coordinated to the K atoms in a transoidal manner \([K–O \text{ bond length is } 2.7199 (13) \text{ }^\AA]\). Reflecting the fact that the K atoms are only partially saturated by the donor molecule in 3 (in comparison with 2), there is an intermolecular interaction with an HMDS methyl group of a neighbouring (KHMDS)\(_2\) unit. This results in the formation of a two-dimensional layer arrangement through K⋯Me interactions \([\text{Fig. 3b and c, } K1⋯C6‘ ~ 3.2226(15) \text{ }^\AA]\). Each \([(\text{KHMDS})_2(\text{THF})_2]\) unit represents a branch point towards four distinct directions in the polymeric two-dimensional sheet, two through its K atoms and two via two methyl groups from each HMDS ligand.

Hydrogen atoms, one disordered component of one SiMe\(_3\) group of 4 and one disordered molecule of toluene of crystallisation of 6 are omitted for simplicity. Displacement ellipsoids are displayed at 35% probability. The dashed lines illustrate K⋯C and K⋯O long interactions. Selected bond distances (\(\AA\)) and angles (\(^\circ\)): for 4, K5–N13 2.8365(16), K5–N14 2.7942(17), K5–N15 2.9744(17), K5–N16 2.9752(17), K5–K6 2.7876(17), K6–N14 2.8765(17), K6–N15 2.9489(19), K6–N16 2.8529(19), K5⋯C71 3.373(3), K5⋯C59 3.397(3), K6⋯C66 3.313(2), N13–K5–N14 98.99(5), N13–K5–N17 135.20(5), N13–K5–N18 120.17(5), N14–K5–N17 115.45(5), N14–K5–N18 123.69(5), N17–K5–N18 63.27(5), N13–K6–N16 133.38(5), N13–K6–N14 98.19(5), N16–K6–N14 111.74(5), N13–K6–N15 118.70(5), N15–K6–N16 62.86(5), N14–K6–N15 133.61(5), N15–K6–N14 80.99(4), K5–N13–K6 81.81(4); for 5, K1–N2 2.884(2), K1–N1 2.908(2), K1–N5 2.959(2), K1–N6 3.035(2), K2–N1 2.785(2), K2–N3 2.878(2), K2–N4 2.764(2), K2–N4 2.878(2), K1–C11 3.369(3), K1–C26 3.185(3), K2–C4 3.223(3), K2–C9 3.180(3), K2–C14 3.346(3), K2–C15 3.299(3), N1–K1–N2 92.04(6), N2–K1–N5 128.12(7), N1–K1–N5 125.61(7), N2–K1–N6 130.71(7), N1–K1–N6 125.71(7), N5–K1–N6 57.22(6), K1–N1–K2 84.78(6), N1–K2–N2 97.37(7), N2–K2–N3 138.81(7), N1–K2–N3 115.26(7), N2–K2–N4 106.44(7), N1–K2–N4 144.64(7), N3–K2–N4 60.14(6), K1–N2–K2 85.62(6); for 6, K1–O1 2.9124(19), K1–O2 2.737(2), K1–O3 2.8024(18), K1–O4 3.121(2), K1–N1 3.073(2), K1–N1' 2.913(2), K1–N1' 2.913(2), K1⋯C6' 3.133(3), O2–K1–O3 61.01(6), O2–K1–O1 59.05(6), O3–K1–O1 84.81(5), O2–K1–O1 91.72(6), O3–K1–O1 79.98(6), O1–K1–N1 150.78(6), O2–K1–N1 138.32(6), O3–K1–N1 160.67(6), O1–K1–N1 105.29(6), O1–K1–N1 83.08(5), N1–K1–N1 96.52(5), O2–K1–O4 88.27(6), O3–K1–O4 55.82(5), O1–K1–O4 56.26(6), N1–K1–O4 128.82(6), N1–K1–O4 116.04(5). The symmetry operation used to generate the equivalent atoms numbered with ′ in 6 is \(-x + 1, -y, -z\).
Derivatives 4-6 crystallised as discrete dimers (Fig. 4a-c). Whilst 4 and 6 are both in the monoclinic space group P2₁/c, 5 is in the orthorhombic S0hnke space group P2₁2₁2₁. TMEDA and its chiral analogue (R,R)-TMCDCA are widely utilised bidentate Lewis donor ligands in the chemistry of alkali metals,⁷⁰⁻⁷² thus surprisingly, 4 and 5 represent the first structural examples of a KHMD5 species solvated by these important dianime ligands. The asymmetric unit of 4 contains three distinct molecules of [(KHMD5)₂(TMEDA)]₆; two of them present some degree of disorder, which hampers their structural discussion. The third is discussed below. Complexes 4-6 resemble the archetypal planar four-membered K₂N₃ metallacyclopentadiene [sum of endocyclic angles, 359° for 4 and 357° for 5] previously seen in 1-3 and in the solvent-free [(KHMD5)]₂.³³,³⁴ In 4 and 5, each K atom is coordinated to two bridging μ-HMDS amidog groups and to the chelating TMEDA and (R,R)-TMCDCA ligands, respectively, resulting in the metals being four coordinate in a distorted tetrahedral geometry [N–K–N range 63.27(5)-135.20(5) and 62.86(5)-133.38(5)° for K5 and K6 in 4, and 52.22(6)-130.71(7) and 60.14(6)-138.81(7)° for K1 and K2 in 5; Fig. 4a and b, respectively]. However, each K in the centrosymmetric 6 binds a tetradeinate 12-crown-4 ligand resulting in six-coordinated metal centres. In 4, the K-NHMD5 bond distances are identical [2.7942(17) and 2.7876(17) Å], whilst for 5 there is a short and long set of K-NHMD5 bonds [short K2–N1 and K2–N2 lengths of 2.785(2) and 2.764(2) Å, and long K1–N1 and K1–N1 lengths of 2.908(2) K1–N2 2.884(2) Å, respectively]. As expected, these are shorter than the K-NTMEDA lone-pair dative interactions with either TMEDA or (R,R)-TMCDCA ligands in 4 and 5, respectively [K-N-TMEDA range 2.8529(19)-2.9489(19) Å in 4 and K-N(R,R)-TMCDCA range 2.878(2)-3.035(2) Å in 5]. The coordination modes of the K atoms in 4 and 5 closely resemble those found in related dimeric [(KDA)₂(TMEDA)]₇³ and [(KTMP)₂(TMEDA)]₇⁴. Turning to 6 (Fig. 4c), the K-NHMDS bond distances are noticeably longer [2.913(2) and 3.073(2) Å] than those for 4 and 5, and as expected longer than that in the donor-free reagent [mean 2.787 Å].³³ This is presumably the result of the different nature and higher denticity of the 12-crown-4 ligand resulting in six coordinate K atoms. The 12-crown-4 ligand coordinates the K metal centres being slightly distorted, thus resulting in four distinct K-O bond lengths. Three of them are in the range 2.773(2)-2.912(2) Å; however, the fourth K-O distance (K1–O4) is considerably longer at 3.121(2) Å. The K atoms are located approximately 2.1 Å above the mean plane of O atoms within the 12-crown-4 molecules. The internal angles at the K atoms in the centrosymmetric K₃N₃ ring are approximately 14° wider than the angles at the N atoms [N–K–N 96.92(5), K–N–K 83.08(5)°], where the latter present an intermediate value between those found in 4 and 5. The mean K–N bond distance of the central (KHMD5)₂ ring of 6 is 2.99 Å. In keeping with the other complexes discussed herein, the coordination spheres of both K atoms in 4-6 are completed by a series of long intramolecular K–C₄H₁₄ interactions [range 3.313(3)-3.397(2) and 3.180(3)-3.369(3) Å in 4 and 5, respectively] while a single K–C₄H₁₄ interaction can be found in 6 for each potassium atom [3.313(3) Å]. Complex 6 is a rare example of a potassium amide 12-crown-4 dimer, only two other examples have been reported with different amides, (2-phenylamido)pyridine⁷⁵ and (trimethylsilylamido)pyridine.⁷⁶

Complexes 7 and 8 both crystallised in the monoclinic system space group P2₁/n, whilst 9 crystallised in the triclinic system P1. Complexes 7-9 (Fig. 5a-c) are essentially isostructural and can be considered as being composed of two [(donor)K–N–K] chains which are linked together though two K-NHMD5 bonds forming a 1 : 2 donor : KHMD5 tetraneuclear discrete arrangement with a central cyclo-dimer (KHMD5)₂ unit. The central K₂N₂ ring is planar in 7-9 (sum of endocyclic angles, 360° for 7-9). Two distinct types of K atoms are found in 7-9 occupying ‘internal’ and ‘external’ positions. Tridentate PMDETA and TMDAE, and the tetradeinate Me₆TREN ligand respectively coordinate the external K atoms in an anti-disposition. The terminal metals are in a distorted tetrahedral environment in 7 and distorted square planar environment in 8. In 9, the tetradeinate amine Me₆TREN coordinates the external K centres in a η⁴-manner, rendering these metals five-coordinated [N–K–N range 62.42(7)-165.97(6)°]. The three N-donor arms emerging from the central N donor in the tripod Me₆TREN ligand are disposed in a plane in which the K atoms occupy a position approximately 1.41 Å above it. The internal K atoms bind to two bridging NHMD5 atoms forming the cyclic (KHMD5)₂ motif (mean K–N-NHMD5 2.83, 2.85 and 2.88 Å for 7, 8 and 9, respectively) and additionally to a bridging NHMD5 atom from a [(KHMD5)(donor)] unit (K1–N2 2.8808(11) Å for 7, K2–N3 2.9254(11) Å for 8 and K2–N5 2.9062(6) Å for 9). The K atoms in the central cyclo-dimer present a distorted trigonal planar geometry in the three examples [range N–K–N 95.93(3)-141.54(4) for 7, N₄–K₂–N₃ 95.65(3)-140.39(3)° for 8 and 96.58(6)-132.40(6)° for 9]. The K-NHMD5 bond distances are similar in 7-9 and as alluded to previously it is they are shorter than the corresponding K-N donorn bond length [mean K-N-PMDETA distance 2.90 Å for 7, mean K-N-TMEDA and K-O-TMEDA distances 2.98 and 2.7362(10), respectively, for 8, and mean K-N-Me₆TREN distance 3.00 Å for 9]. Additionally, the K atoms in 7, 8 and 9 show stabilizing long K–C contacts with methyl groups from the HMDS and donor ligands [K–C range 3.3232(17)-3.3663(3) for 7, 3.3147(14)-3.3353(15) for 8, 3.239(4)-3.402(3) Å for 9]. A search of the Cambridge Crystallographic Database reveals only four solid state structures with either PMDETA or Me₆TREN coordinating to a K metal centre, including benzyl potassium [3,5-Me₂C₆H₃CH₂K].⁵⁵,⁷⁸

In an effort to prepare and characterise the solid state structures of monomeric KHMD5 species we used TMDAE and the heptadentate TMEEA donor molecules in 2:1 and 1:1 donor:HMDS molar ratios yielding 10 and 11, respectively. X-ray crystallographic analysis reveals that 10 crystallises in the monoclinic space group P2₁/a, whilst 11 crystallises in the triclinic space group P1. The structures of 10 and 11 (Fig. 6a and b, respectively) consist of discrete solvated monomeric species of KHMD5 containing two molecules of TMDAE and one molecule of the multidentate TMEEA molecule coordinating the K atom.
metal centres, respectively. Two chemically identical but crystallographically distinct molecules of 10 are observed within its asymmetric cell; however, for simplicity and due to disorder in one of the molecules, the structural parameters of only one molecule will be discussed. The K metal centre is seven-coordinate to the TMEDA and HMDS ligands in 10, increasing its coordination number to eight in 11. The salient structural feature of 10 and 11 is that these compounds are monomeric. In keeping with the tendency observed in the previous examples, the K-NHMDS bond lengths found in 10 are shorter than the K-N\textsubscript{donor} bond distances [K2-N6\textsubscript{HMDS} 2.794(3), mean K-N\textsubscript{donor} 3.208 Å] with K-O bond distances of 2.814(2) and 2.824(2) for K2-O3 and K2-O4, respectively. Also, in 11, the K-NHMDS bond length [K1-N2 2.7889(8) Å] is shorter than the K-N\textsubscript{donor} [K1-N1 3.1364(9) Å], and noticeably one of the K-O bond lengths is shorter than K-NHMDS bond distance [K1-O1 2.7613(8) Å] while the rest of the K-O bond lengths are in the range 2.8131(9)–3.3145(10) Å. One example of a solvated monomeric species [KHMS[18-crown-6]] was previously crystallographically characterised\cite{19} where the K atom is hepta-coordinated to the chelating crown ligand and HMDS group. Both compounds, 10 and 11, crystallise from toluene solutions. The affinity of heavy alkali metals to engage \pi-interactions with arenes is well known,\cite{20,21,22,23} however, in the presence of the corresponding multidentate ligands TMDA and TMEEA in 10 and 11, respectively, there is no interaction with the arene in the solid-state structures.

**NMR spectroscopic studies**

Crystalline compounds 1–11 were studied by \textsuperscript{1}H, \textsuperscript{13}C and DOSY NMR spectroscopies in CD\textsubscript{6} solution. The \textsuperscript{1}H and \textsuperscript{13}C NMR spectra of 1–11 showed two distinct set of signals corresponding to the Lewis base donor of choice and the HMDS group. In general, the Lewis donor ligand : HMDS ratio found for the TMEDA species is marginally shifted downfield for the THF-solvate (0.16 ppm). For the dimeric complexes containing the bidentate 12-crown-4, R\textsubscript{1}-TMCDA, R\textsubscript{2}-(R)-TMCDA, and (R,R)-TMCDA, 4 and 5, the HMDS singlet appears only slightly shifted downfield (0.23 ppm in both) with respect to 1–3, and is similar to that found for the TMEDA species 4 (0.24 ppm). However, the \textsuperscript{1}H NMR resonance for the HMDS ligand for the 12-crown-4,
Conclusions

The solid and solution structural chemistry of KHMDS has been developed by exploring its coordination chemistry with a series of Lewis donor molecules. In the solid state, four different aggregation forms of KHMDS have been found, namely, a linear polymeric chain array (in the presence of toluene), two-dimensional polymeric layer arrangement (with THF), dimeric arrangements (with toluene, TMDA, R,R-TMCD and 12-crown-4), tetranuclear aggregates (with PMDETA, TMDA and Me₆TREN), and discrete monoceric species (with TMDA and TMEA). Solution studies by DOSY NMR spectroscopy in [D₆]THF and arene (C₆D₆ and D₆-toluene) reveal that monomerisation of KHMDS and displacement of the Lewis donor by these solvents occur in all the examples studied at ambient temperature.

Experimental

General procedures

All manipulation and reactions were performed under an atmosphere of dry pure argon gas using standard high vacuum Schlenk and glove box techniques. n-Hexane, toluene and tetrahydrofuran (THF) were distilled under reflux with sodium metal and benzophenone under a nitrogen atmosphere. Toluene was additionally stored over activated 4 Å molecular sieves. C₆D₆, [D₆]toluene and [D₆]cyclohexane were degassed and dried over activated 4 Å molecular sieves. [D₆]THF was stored over a potassium metal mirror. KHMDS was purchased from Aldrich and used as received. N,N,N′,N″-Tetramethylethlenediamine (TMEDA), N,N,N″,N″″-penta-methyldiethylenetriamine (PMDETA) and N,N,N″,N″″-tetramethyldiaminoethy ether (TMDA) were purchased from Aldrich, distilled with CaH₂ under a nitrogen atmosphere and stored over activated 4 Å molecular sieves. Tris[2-(2-methylthoxyethoxy)ethyl]amine (TMEA) and 12-crown-4 were purchased from Aldrich and stored over activated 4 Å. Tris[2-dimethyl (amino)ethyl]amine was prepared by a previously reported method and stored over activated 4 Å molecular sieves. NMR spectra were collected on a Bruker AV400 MHz spectrometer operating at 400.1 and 100.6 MHz for 1H and 13C, respectively. 1H and 13C [3]H NMR chemical shifts are expressed in parts per million (δ ppm) and referenced to residual solvent peaks. Microanalyses were obtained using a PerkinElmer 2400 elemental analyser.
X-ray crystallography

Crystallographic data were collected at 123(2) K on Oxford Diffraction Xcalibur (Mo-Kα radiation, λ = 0.71073 Å, for 3, 4, 6, and 11) and Gemini (Mo-Kα radiation, λ = 0.71073 Å, for 9; Cu-Kα radiation, λ = 1.5418 Å, for 1, 2, 5, 7, 8 and 10) diffractometers. The structures were solved and refined to convergence on Ρ² and against all independent reflections by full-matrix least-squares using SHELXS and SHELXL programs, respectively. All non-hydrogen atoms were refined anisotropically and hydrogen atoms were geometrically placed and allowed to ride on their parent atoms. The THF ligand in 3, SiMe₃ groups and a TMEDA ligand in 4, the chelate group of 10, and toluene molecules of crystallisation in 6 and 9 were modelled as disordered over two sites with the geometry and displacement parameters of these groups restrained to approximate typical values. Selected crystallographic and refinement details are provided in Tables S1 and S2.

Synthesis of [(KHMDS)₂(toluene)]∞ (1). KO’Bu (0.56 g, 5 mmol) was reacted with LiHMDS (0.84 g, 5 mmol) in n-hexane (20 mL) for 5 days. After this time, the solvent was removed under vacuum and the product was extracted in hot toluene (30 mL). Suitable crystals of 1 for an X-ray diffraction study were grown by cooling down a hot solution of 1 in a 2:1 mixture of n-hexane/toluene (9 mL) in a hot water bath (24 h). The crystalline material was filtered, washed with cold n-hexane (5 mL) and dried under vacuum for 10 min. Yield: 0.44 g, 0.94 mmol, 38%. In agreement with ¹H NMR and micro elemental analyses toluene is partially removed (approximately 25%) during isolation of 1. ¹H NMR (400.1 MHz, C₆D₆, 300 K): δ 0.13 (s, 36 H, Me₃Si), 2.11 (s, 3 H, Me-toluene), 7.03 (m, 3 H, toluene), 7.12 (d, 2 H, J_HH = 8.0 Hz, toluene). ¹³C{¹H} NMR (100.6 MHz, C₆D₆, 300 K): δ 7.2 (Me₃Si), 21.4 (Me-toluene), 125.7 (para-CH, toluene), 128.6 (meta-CH, toluene), 129.3 (ortho-CH, toluene), 137.9 (ipso-C, toluene). Anal. calc’d (found) for C₁₂H₃₆K₂N₂Si₄C₅.25H₆: C, 44.26 (45.44); H, 9.04 (9.25); N, 5.23% (5.69%).

Synthesis of [(KHMDS)₂(toluene)] (2). KHMDS (1.00 g, 5 mmol) was taken up in hot toluene (10 mL) and then filtered to give a colourless solution. This solution was then concentrated (ca. 3–5 mL) and placed at −27 °C (12 h) to give crystals of 2 suitable for an X-ray crystallographic study. The crystalline material was filtered, washed with cold n-hexane (5 mL) and dried under vacuum for 10 min. Yield: 0.58 g, 0.92 mmol, 46%. In agreement with ¹H NMR and micro elemental analyses toluene is partially removed (approximately 25%) during isolation of 2. ¹H NMR (400.1 MHz, C₆D₆, 300 K): δ 0.13 (s, 18 H, Me₃Si), 2.11 (s, 3 H, Me-toluene), 7.02 (m, 2 H, toluene), 7.13 (d, 2.5 H, J_HH = 8.0 Hz, toluene). ¹³C{¹H} NMR (100.6 MHz, C₆D₆, 300 K): δ 7.2 (Me₃Si), 21.4 (Me-toluene), 125.7 (para-CH, toluene), 128.6 (meta-CH, toluene), 129.3 (ortho-CH, toluene), 137.9 (ipso-C, toluene). Anal. calc’d (found) for C₁₂H₃₆K₂N₂Si₄C₆.4H₁₂.₈O₁.₆: C, 42.97 (43.86); H, 9.56 (9.94); N, 5.45% (5.41%).

Synthesis of [(KHMDS)₂(TMEDA)]∞ (4). TMEDA (0.6 mL, 4 mmol) was added via a syringe to a stirred solution of KHMDS (0.80 g, 4 mmol) in n-hexane (20 mL) producing a slightly cloudy reaction mixture after 20 min at room temperature. The reaction mixture was then heated and filtered to give a colourless solution which was concentrated under vacuum (10 mL). Crystals of 4 suitable for an X-ray diffraction study were obtained by cooling down the resulting solution at −27 °C (12 h). The crystalline material was filtered, washed with cold n-hexane (5 mL) and dried under vacuum for 10 min. Yield: 0.58 g, 0.92 mmol, 46%. ¹H NMR (400.1 MHz, C₆D₆, 300 K): δ 0.23 (s, 18 H, Me₃Si), 2.04 (s, 12 H, Me-TMEDA), 2.05 (s, 4 H, CH₂-TMEDA). ¹³C{¹H} NMR (100.6 MHz, C₆D₆, 300 K): 7.3 (Me₃Si), 45.6 (Me-TMEDA), 57.6 (CH₂-TMEDA). Anal. calc’d (found) for C₁₂H₃₆K₂N₂Si₄C₆.4H₁₂.₈O₁.₆: C, 45.66 (45.95); H, 10.86 (11.42); N, 13.31% (13.34%).

Synthesis of [(KHMDS)₂(R,R)-TMCDCA] (5). (R,R)-TMCDCA (0.38 mL, 2 mmol) was added via a syringe to a stirred solution of KHMDS (0.40 g, 2 mmol) in n-hexane (20 mL) producing a slightly cloudy reaction mixture after 20 min at room temperature. The reaction mixture was then filtered to give a colourless solution which was concentrated under vacuum (5 mL). Crystals of 5 suitable for an X-ray diffraction study were obtained by cooling down the resulting solution at −27 °C (12 h). The crystalline material was filtered, washed with cold n-hexane (5 mL) and dried under vacuum for 10 min. Yield: 0.34 g, 0.46 mmol, 46%. ¹H NMR (400.1 MHz, C₆D₆, 300 K): δ 0.23 (s, 18 H, Me₃Si), 0.89 (s, 4 H, β-CH₂(R,R)-TMCDCA), 1.60 (s, 4 H, γ-CH₂(R,R)-TMCDCA), 2.19 (s, 12 H, Me-(R,R)-TMCDCA). ¹³C{¹H} NMR (100.6 MHz, C₆D₆, 300 K): δ 7.4 (Me₃Si), 23.9 (β-CH₂(R,R)-TMCDCA), 25.8 (γ-CH₂(R,R)-TMCDCA). Anal. calc’d (found) for C₃₂H₈₀K₂N₄Si₄C₆: 51.97 (52.01); H, 10.90 (10.74); N, 11.36% (11.40%).
study were obtained at −27 °C (3 days). In agreement with 1H NMR and microelemental analyses the toluene solvent molecule of crystallisation present in the crystal lattice of 6 is removed upon isolation. Yield: 0.36 g, 0.48 mmol, 96%. 1H NMR (400.1 MHz, C6D6, 300 K): δ 0.43 (s, 18 H, MeSi), 3.06 (s, 16 H, CH2). 13C{1H} NMR (100.6 MHz, C6D6, 300 K): δ 7.4 (MeSi), 67.1 (C2). Anal. calcd (found) for C28H68K2N2O8Si4: C, 42.96 (41.99); H, 10.09 (9.82); N, 3.73% (3.43%).

Synthesis of [KHMDS(TMDAE)]2(10). TMDAE (0.76 mL, 4 mmol) was added via a syringe to a stirred gently heated suspension of KHMDS (0.40 g, 2 mmol) in hexane (20 mL) to give a pale yellow solution. The solution was concentrated (5 mL) and crystals of 11 suitable for an X-ray diffraction study were obtained at −27 °C (5 h). The crystalline material was filtered, washed with cold n-hexane (5 mL) and dried under vacuum for 15 min. Yield: 0.65 g, 1.25 mmol, 62%. 1H NMR (400.1 MHz, C6D6, 300 K): δ −0.08 (s, 8 H, MeSi), 2.20 (s, 12 H, MeO-TMDAE), 2.42 (t, 4 H, 3JHH = 5.8 Hz, CH2N-TMDAE), 3.51 (t, 4 H, 3JHH = 5.8 Hz, CH2-O-TMDAE). 13C{1H} NMR (100.6 MHz, C6D6, 300 K): δ 7.4 (MeSi), 46.2 (MeO-TMDAE), 60.0 (CH2N-TMDAE), 70.0 (CH2-O-TMDAE). Anal. calcd (found) for C28H51KN2O6Si2: C, 50.82 (50.60); H, 11.24 (11.12); N, 13.47% (13.77%).

Synthesis of [KHMDS(TMEEA)] (11). TMEEA (0.84 mL, 2 mmol) was added via a syringe to a stirred white suspension of KHMDS (0.40 g, 2 mmol) in n-hexane (20 mL) to give a brown oily material. The solvent was removed under vacuum until dryness and toluene (4 mL) was added to give a brown solution. Suitable crystals of 10 for an X-ray diffraction study were grown from a 1:5 mixture of n-hexane/toluene (6 mL) at −27 °C (12 h). The crystalline material was filtered, washed with cold n-hexane (10 mL) and dried under vacuum for 15 min. Yield: 0.72 g, 1.38 mmol, 69%. 1H NMR (400.1 MHz, C6D6, 300 K): δ 0.49 (s, 18 H, MeSi), 2.25 (t, 6 H, 3JHH = 5.0 Hz, CH2-N), 3.16 (t, 6 H, 3JHH = 5.0 Hz, N−CH2−CH2−O), 3.22 (s, 9 H, MeO), 3.31 (m, 6 H, CH2−O), 3.63 (m, 6 H, O−CH−CH2−O). 13C{1H} NMR (100.6 MHz, C6D6, 300 K): δ 7.4 (MeSi), 55.2 (CH2−N), 58.9 (MeO), 68.6 (N−CH2−CH2−O), 70.2 (O−CH−CH2−O). Anal. calcd (found) for C21H51KN2O6Si: C, 48.24 (48.42); H, 9.83 (10.18); N, 5.36% (5.63%).

Acknowledgements

We would like to thank Prof. Robert Mulvey and Prof. Eva Hevia for useful and insightful discussions and the financial support of the Engineering and Physical Science Research Council (EPSRC) (Career Acceleration Fellowship, EP/J001872/1 and EP/L001497/1).
