Arylidene indanone scaffold: medicinal chemistry and structure–activity relationship view

José C. J. M. D. S. Menezes†

Arylidene indanone (AI) scaffolds are considered as the rigid cousins of chalcones, incorporating the α,β-unsaturated ketone system of chalcones forming a cyclic 5 membered ring. They are generally synthesized from 1-indanone and benzaldehydes via an aldol reaction. The furnished molecules have been explored as inhibitors of cholinesterases towards the treatment of Alzheimer’s disease, as tubulin depolymerizing agents, as inhibitors of breast cancer and leukemia, inhibitors of dual specificity phosphatase (DUSP), as antimalarials, and for many other uses. This review is an effort to highlight the biochemical effects of arylidene indanones designed from natural or known drug compounds, discuss their structure–activity relationships (SAR), and correlate them with related chalcones providing insights for further development of this scaffold.

1. Introduction

Natural indanones like pterosin P 1 from fern (Pteridium) species,1-3 4-hydroxy-7-methylindanone 2 and 7-formyl-3-methoxy-5-methylindanone 3 from marine cyanobacterium4,5 have shown antibacterial,4 antispasmodic,6 inhibition of hypoxia-induced activation of vascular endothelial growth factor (VEGF)5 and cytotoxic activities.3 The 4,5,6-trimethoxyindanone-estradiol hybrid 4 was more potent against MCF-7 breast cancer cells in comparison to the chalcone–estradiol precursor 5 (see Fig. 1 for structures).7

Arylidene indanones (AI) are mostly synthetic molecules, consisting of the natural/synthetic indanone core (see the part of the structure in green lines) and an aryl group linked through an exocyclic double bond at the 2-position of this indanone core (for the numbering system see Fig. 1). This AI scaffold often connoted as cyclic chalcone can be considered as rigid cousins or homologs of chalcones, incorporating the α,β-unsaturated ketone (red dashed circles) into a cyclic 5 member ring which is attached to the 2-position of chalcone ring (red arrow) and to the α-position of the unsaturated bond (blue arrow), making it

Fig. 1 Natural and synthetic indanones and the basic similarities between arylidene indanone and its cousin, the chalcone.

José C. J. M. D. S. Menezes completed his PhD in synthetic Organic Chemistry from Goa University, India in 2009 with Prof. S. P. Kamat and a post-doc with Prof. José A. S. Cavaleiro working on natural and synthetic porphyrins from October 2010–2013, at the Department of Chemistry, University of Aveiro, Portugal. He has published 20 papers in peer reviewed international journals. His research interests are the design of new molecules using natural molecule templates, synthesis and applications in biology. Presently he is working as a Tokyo Biochemical Research Foundation post-doctoral fellow at the Department of Pharmacy, Nagasaki International University, Japan.
a planar/rigid exocyclic \(\alpha,\beta\)-unsaturated ketone system. Chalcones, belong to the class of flavonoids and have been explored as anti-infective, anti-inflammatory and anti-cancer agents.\(^{9,9}\)

The interaction of natural or synthetic chalcones with molecular targets like tubulin, kinases, oxidoreductases, hydrolases, esterases,\(^{16}\) and cell cycle blockers have been reviewed.\(^{11}\) Recent developments of the synthetic chalcone scaffold with different heterocyclic rings or hybrids with other natural compounds for various therapeutic roles have been compiled.\(^{12}\)

The position of the arylidine ring with respect to the indanone core results in a planar structure and allows transmission of the electron donor effects of the substituents via the double bond onto the carbonyl group of indanone, thus lowering the wavenumber-frequency more effectively compared to chalcones.\(^{13}\) Higher values were observed in the \(^{13}\)C NMR of the \(\alpha,\beta\)-unsaturated ketone carbons of AIs compared with chalcones which had similar electron donating substituents in the aryl ring.\(^{11,14}\) The position of absorption maxima (UV-vis) for AI is higher in comparison with chalcones having similar para-substituents in the aryl ring indicating the strongest conjugation due to its planar structure.\(^{15}\) The lipophilicity of AI can be increased by geometric inversion of the double bond from the \(E\) to \(Z\)-isomer which occurs due to UV-light.\(^{16}\) In the case of chalcones, the double bond can have either the \(s\text{-cis}\) or \(s\text{-trans}\) conformation while in the case of AI the molecule is forced to adopt the \(s\text{-cis}\) conformation due to the cyclic ring. The introduction of an \(\alpha\)-substituent on the double bond makes the chalcone adopt the \(s\text{-trans}\) conformation and this was explored to design potent tubulin inhibitors.\(^{17,18}\)

Retrosynthesis of AI leads to 1-indanones (natural or synthetic) which are assembled from phenyl/aryl propionic acid via cyclization reactions using polyphosphoric acid,\(^{19}\) methane sulphonic acid,\(^{20}\) Friedel–Crafts acylation under microwave heating and ultrasonication,\(^{21,22}\) and Nazarov cyclization of chalcones.\(^{7}\) Further reaction of suitably substituted 1-indanone with benzaldehyde derivatives under aldol conditions or potassium carbonate and microwave irradiation leads to the synthesis of AI.\(^{23-24}\) Substitution in the indanone ring as well as in the benzaldehyde moiety has furnished AI scaffolds having therapeutic effects against breast cancer,\(^{25}\) leukemia,\(^{26}\) and Alzheimer’s disease,\(^{27}\) AI scaffolds causing inhibition of DUSP\(^{28,29}\) and AI scaffolds acting as potential antimalarial agents.\(^{30,31}\) This review discusses the various therapeutic roles of AIs, their structure–activity relationships and correlates them wherever possible with structurally similar or related chalcones. The web-based Molinspiration software and the related molecular properties (using the Lipinski rule) were utilized to predict theoretical milog \(P\) (octanol–water partition coefficient) of selected groups of molecules.\(^{32,33}\)

### 2. Effect of AI in Alzheimer’s disease

Alzheimer’s disease \((AD)\) is a neurodegenerative disorder which is the cause of dementia (loss of memory) in the later stages of adult life and its prevalence is estimated to rise up to 106 million by 2050.\(^{34}\) The neuropathological features of AD are extracellular deposits of amyloid beta peptide \((\text{A}\beta)\) called amyloid plaques and hyperphosphorylated neurofibrillary tangles \((\text{NFTs})\).\(^{35}\) Cleavage of the amyloid protein precursor \((\text{APP})\) by secretases \((\alpha,\beta,\gamma)\) results in the production of various species of \(\text{A}\beta\) which due to non-clearance from the brain form \(\text{A}\beta42\) oligomers which hydrophobically self-aggregate and give rise to diffuse senile plaques \((\text{SPs})\).\(^{36}\)

The human brain has two major cholinesterases; acetylcholinesterase \((\text{AChE})\) and butyrylcholinesterase \((\text{BuChE})\) both differing in their genetics, structure, and kinetics. In patients with AD, BuChE is found in neurons and glial cells as well as in neuritic plaques and tangles.\(^{26}\) Acetylcholine, a neurotransmitter molecule linked with intellectual abilities decreases in the brain due to enhanced acetylcholinesterase activity resulting from AD or old age. The acetylcholinesterase \((\text{AChE})\) enzyme structure determined for \textit{Toxopoma californica} \((\text{Tc})\) consists of a catalytic triad \((\text{having residues Ser200, His440, and Glu327})\) and a peripheral anionic site \((\text{PAS})\).\(^{37}\) The active site also contains an anionic subside consisting of the key residue Trp84 located near the bottom of the cavity. This site interacts with the quaternary ammonium group of acetylcholine substrates and other ligands via cation–π interaction.\(^{37}\) While the PAS of the acetylcholinesterase enzyme is located at the entrance of the narrow catalytic gorge which serves as a transient binding site for substrates entering the active site. The \(\text{A}\beta\) peptide interacts with the PAS resulting in the unfolding of these proteins and the formation of plaques.\(^{37}\) Donepezil hydrochloride \(6\) \((\text{see Fig. 2})\) interacts with these dual binding sites of the AChE enzyme\(^ {38}\) and is the presently used drug \((\text{Aricept})\) for all stages of Alzheimer’s disease.\(^ {39}\) Several other drugs like rivastigmine \(7\), galantamine \(8\), memantine \(9\) and the combination of donepezil and memantine have been approved.\(^ {30}\) Hybrid compounds for the treatment of AD have been derived by combining fragments or drug molecules like \(6\) and tacrine \(10\);\(^ {40,41}\) \(8\) and \(9\);\(^ {42}\) and natural molecules like curcumin, berberine, furulic and caffeic acid,\(^ {43-44}\) chalcones and coumarin derivatives,\(^ {45}\) and resveratrol and cloquinaol.\(^ {44}\)

Most of the compounds discussed in this section have been derived from the indanone core of \(6\) with modification in the 5,6-position or substitution of arylidine with fragments from

![Fig. 2](https://example.com/diagram.png) Drugs approved for the treatment of Alzheimer’s disease.
other drugs. Hybrid molecules designed by combining the phenyl-N-methylbenzylamine fragment of AP2238 (see the structure and fragment in the blue ellipsoid; Fig. 3), with the indanone core of donepezil 6 (see the red dashed box in Fig. 2) resulted in several new indanone derivatives with potencies against AChE (5 examples).45

Although the 5,6-dimethoxy groups of donepezil have efficient interaction with the PAS of the cholinesterase enzyme, the methoxy at 6-position of indanone 11a gave a hydrophobic interaction with the side chain of the Leu289 residue and was more potent for AChE inhibition.45 Further modification of the 6-position by introducing alkyl chains of varying lengths having different terminal amine groups was studied for efficient interaction with the PAS of AChE (12 examples). The optimum length of the alkyl spacer was 5 carbons, with the terminal N,N-diethyl substituent (11b). The ability of 11b to prevent AChE-induced and self Aβ aggregation was noted.45

APP is cleaved by a β-secretase known as the β-site APP cleaving enzyme, BACE1, and this is the rate-limiting step in the generation of Aβ peptide fragments.35 Inhibition of this enzyme was attempted by retaining the basic structure of 11b and introducing piperazine on the penty1 side chain with a disubstituent on the second nitrogen (8 examples). Substitution with bis(4-fluorophenyl)methyl resulted in the molecule 11c which showed potent activity against BACE1 (IC50 = 2.49 M).36 Docking studies of 11c with the BACE1 enzyme showed interaction with amino acid residues outside the binding pocket but it was unable to enter the narrow gorge of hAChE due to the bulky nature of the bis(4-fluorophenyl)methyl group and it had low neurotoxicity in human neuronal SH-SY5Y cells.46

Meng and co-workers evaluated the modification of the 6-position of indanone by derivatives of the type 12 (13 examples).39 The introduction of the piperidinyl ethoxy substituent at the 6-position of indanone 12a and pyridinyl methylene at the 2-position made indanone 12b more potent than donepezil 6 and the starting indanone 12a (see Fig. 3 and Table 1 for IC50 values). The introduction of the piperidinyl ethoxy group in the 6-position of the starting indanone 12a had no improvement on the inhibition efficiency indicating the crucial nature of the double bond for the activity. Chelation of biometals like Cu2+, Fe3+ and Zn2+ is an important strategy for treatment of AD since these metals accumulate on the formation of amyloidal plaques and SPs.53,54 Metal chelation studies using 12b and a solution of Cu2+, Fe3+ and Zn2+ indicated a blue shift using UV-vis spectrophotometry (a decrease in wavelength or a move towards the blue end of the visible spectrum) from 360 nm to 352 nm, 346 nm, and 357 nm respectively.49 The piperidinyl ethoxy arm of 12b (2 carbon spacer) functions/mimics as the biometal chelator group and is present in clioquinol (see the dashed oval shape for the clioquinol structure in Fig. 3) and is used as a reference for these studies. This fact was fortified by using a compound with a carbon spacer of 5 (C = 5) which did not show any metal chelation.49 In the case of clioquinol, the donor groups N and O may form a bidentate chelate which can form a five-membered ring complex with bivalent metals and the five-membered ring complex formed during chelation is more effective, compared to any other ring size.55 The benefits/challenges of using chelating therapy for AD have been given an overview, which includes clioquinol among other molecules.51,56

The 6-piperidinylethoxy-5-methoxy indanone moiety from 12b was retained while the 4-position on the arylidene ring was varied to design “multi-target one ligand” molecules (11 examples). Derivatives 13a–13c (Fig. 3) indicated a higher potency for inhibition of AChE with nanomolar IC50 values compared with 10 and similar ones to 6 (see Table 1 for IC50 values).57 The substituent at the 4-position of the phenyl ring showed no relevant role as the potencies were similar for compounds 13a–13c.36 Inhibition of Aβ aggregation by 13a and 13b was noted. Antioxidant activity was highly diminished for 13c highlighting the importance of the amino group at the 4-position on the phenyl ring.31 The chalcone derivative 13d (Fig. 3) having 2-pyrrolidinyl ethoxy at the 4’-position and a fluoro group at the 4-position showed potency for AChE.

Fig. 3 Cholinesterase inhibitor hybrids derived from donepezil and AP2238.
compared to BuChE and this was correlated by docking analysis which showed a dual interaction with the catalytic site and the PAS of the AChE enzyme.\(^\text{47}\)

The bis(4-fluorophenyl)methyl piperazine group (see R of 11c in Fig. 3) was introduced on the 4-position of the arylidene group (14a; Fig. 4) providing the most potent acetylcholinesterase inhibition amongst the 15 tested compounds.\(^\text{48}\) The pyrimidine 14b and 3-furoyl groups 14c also gave potent acetylcholinesterase and butyrylcholinesterase inhibition compared with 6 (see Table 1).\(^\text{48}\)

The substitution on the piperazine ring by \(\text{N},\text{N}\)-dimethyl aminopropyl group gave the most potent molecule 14d having AChE inhibition activity (among 24 examples) and was compared with standard reference donepezil 6 and tacrine 10.\(^\text{50}\)

Incorporating the \(\text{N},\text{N}\)-dimethyl amino side chain similar to that found in rivastigmine 7 (Fig. 2), at the para position of the benzene ring and varying the substituents to diethyl, pyrrolidine and piperidine resulted in 20 compounds of the type 15a–d (see Fig. 4). The para isomers were more effective than their meta isomers. The diethyl 15b and pyrrolidine 15c AIs were more potent compared with dimethyl amino 15a, piperidine 15d, and rivastigmine 7 (see IC\(_{50}\) values in Table 1). In general, the AIs were more potent than their reduced counterparts and selective for AChE over BuChE.\(^\text{52}\)

The active indanone derivative 15b improved the acquisition and memory loss induced by scopolamine\(^\text{52},\text{56}\) sodium nitrite, and ethanol\(^\text{56}\) and showed neuroprotective functions in PC12 cells.\(^\text{56}\)

Interaction of the diethylamine nitrogen of 15b with the Trp84 residue situated at the bottom of the AChE gorge and of the indanone ring with the indole ring of Trp279 at the top of the gorge was shown by docking studies based on the X-ray crystal structure of the TcAChE–E2020 (donepezil) complex (see Fig. 5 reproduced with permission from Elsevier Masson SAS).\(^\text{52}\) These docking interactions were verified by independent QSAR and docking studies of 15b which revealed similar findings.\(^\text{57}\) Another recent docking study also verified these findings.

\(^a\) Human recombinant BACE1 (hBACE1) using FRET assay; ND-not determined.
inhibition activities, the position of aryl ring didn’t show promising AChE or BuChE inhibition activities, pointing out the importance of methylene substitution at the 4-position of aryl ring as seen in 15c and 15b.

Self-mediated Aβ1–42 aggregation which is implicated in the progression of AD, was targeted by 16a (Fig. 4; highest potency of 80.1% at a concentration of 20 μM) which was among 19 derivatives having the N,N-diethylamino and pyrrolidine groups directly attached to the 4-position of aryl ring. The calculated milog P values of 16c and 16d (3.24) are higher than 16e’ and 16d’ (1.22) indicating an increase of lipophilicity due to the benzyldiene moiety.

Substitution on the arylidene ring at the 4′-position with bromo (16e) and methyl (16f) gave potent results among 22 tested compounds. These compounds were more potent for MAO-B than as MAO-A inhibitors. The lipophilic 5-methoxybenzylidene indanones 16g improved the MAO-B inhibition value compared to that observed for 16c. The modification of the arylidene group using hetero arylidene moieties like pyridine, furan and thiophene gave the equipotent compound 16h which has a 5-bromo-2-furan substituent. 5-Chalcones 16i and 16j having some structural similarities with the AIs discussed above were more potent for MAO-B compared to their use as MAO-A inhibitors (see Table 2).

Detection of senile plaques (SPs) which are composed of Aβ protein aggregates and NFTs may help in the diagnosis of AD. The importance of single photon emission computed tomography (SPECT) radiotracers for imaging amyloid plaques in the brain of AD patients has been an active area of research using different types of molecules. Iodinated imaging probes e.g., the radioactive labeled Pittsburgh compound B (PIB), and its 131I analog are routinely used for detection (Fig. 7). AIs 17a–17d (Fig. 7) were evaluated as amyloid imaging agents in vitro and in vivo since they qualify as a neutral molecule possessing at least two phenyls (or heterocyclic) rings and a linker and are in conjugation with each other, and the molecule as a whole has a hydrophobic, planarized π system.

A binding affinity assay with human AD brain homogenates showed that 17a has the highest binding constant (Kd = 16 ± 1 nM) while the 5-methoxy 17b showed an increase in the binding constant (Kd = 21 ± 1 nM). The iodinated derivatives 17c–17d were bound to the SPs in less than 20 minutes but were unable for in vivo experiments due to their high binding constants (>20 nM) while 17d had excellent fluorescence staining in SPs. Radioiodination derivatives 17c [125I] and 17d [125I] showed good brain uptake/penetration (2.74% and 4.58% ID g\(^{-1}\)) (injected dose per gram) respectively; 2 minutes after intravenous injection), clearance rates (0.40% and 0.45% ID g\(^{-1}\) respectively; 60 minutes) and labeling of SPs with as intense signals as those of 4-(6-iodoimidazo[1,2-α]pyridin-2-yl)-N,N-dimethylaniline (IMPY). They were also more stable in human brain homogenates (17c [125I]; 98% for 60 min) compared to those in mice (17c [125I]; 13% for 30 min).

Although the dihydroxy-substituted 16a showed MAO-B inhibition, several new compounds like 16c–16h (Fig. 6) similar to this scaffold have shown inhibition with monohydroxy/methoxyl substitution at the 5-position. The 5-monohydroxy compound 16c showed better inhibition of MAO-B compared to the 6-hydroxy isomer 16d (see IC\(_{50}\) values in Table 2). In a previous study, the appropriate benzyloxy substituent on the 5 or 6-position of the indanone ring was shown to have influence in the inhibition of MAO-B over MAO-A. Moreover, a comparison of the MAO-B inhibition data of the 5 and 6-hydroxyindanones 16c and 16d (ref. 63) with the aryldiene indanones 16e and 16f indicates that the inhibition potency improved with the introduction of the benzyldiene moiety. The calculated milog P values of 16e and 16f (3.24) are higher than 16e’ and 16d’ (1.22) indicating an increase of lipophilicity due to the benzyldiene moiety.
Modification of the same scaffold of 17a-17d, with the incorporation of a methoxy group at the 6-position and iodine at the 5-position, improved the binding affinity \(K_i = 28.63 \text{ nM}\) of 17e, in comparison to 17c and 17d (see discussion in the previous paragraph and Fig. 7). Furthermore, 17e showed good brain uptake/penetration \(5.29\% \text{ ID g}^{-1}/\text{C0}^{-1} \text{; 2 minutes after intravenous injection}\) which can be explained by the increase of lipophilicity due to the methoxy group and correlated with the partition coefficient value of \(\log P = 3.45\). The stability of radio-iodinated 17e in human AD brain homogenates was higher \((17e \text{[}^{125}\text{I}] ; 98\% \text{ for 60 min})\) compared to those in mice \((17e \text{[}^{125}\text{I}] ; 9.9\% \text{ for 30 min})\).46

### 3. Arylidene indanones as inhibitors of tubulin assembly

Microtubules are dynamic polymers, stiff hollow cylindrical structures with an outer diameter of about 25 nm and a wall approximately 5 nm thick, formed from globular protein subunits of \(\alpha\)-tubulin and \(\beta\)-tubulin of about 55 kDa each that are tightly bound together by noncovalent bonds.7 They assemble/disassemble continuously in the cell filling the cytoplasm and are equipped to transmit signals throughout the cell and interact with signaling proteins and organelles. The

**Fig. 6** AI and chalcones tested as inhibitors of MAO-A/B.

**Fig. 7** Amyloid imaging probes and potential AI and chalcones as imaging probes for \(\beta\)-amyloid plaques.
nucleation–elongation pathway for the polymerization of αβ-tubulin dimers occurs by forming a short polymer nucleus to which subunits are added non-covalently. The association of tubulin subunits to the growing polymer is faster compared to the depolymerization and at the steady state; there is a balance between these two processes. This dynamic steady state, wherein the microtubules alternate between a period of formation and disassembly is termed dynamic instability. Chemical agents interact with microtubules promoting either disassembly or assembly, thereby blocking microtubule dynamics, modifying biological processes and signaling pathways and leading ultimately to apoptosis.74

Indanocine 18 was identified as a potent microtubule-depolymerizing agent with anti-proliferative activity by the National Cancer Institute’s (NCI) Therapeutic Program (see Fig. 8).75 Indanocine 18 blocked tubulin polymerization, induced apoptosis in stationary phase multidrug resistant cancer cells and didn’t affect the viability of non-proliferating cells.76 Assessment of the in vivo antitumor activity of 18 was hampered due to poor water solubility (soluble in DMSO up to 20 mM and up to 100 μM in aqueous solutions). This solubility issue was overcome by designing the 4-phosphate analog 18a, having similar in vitro activity but reduced comparatively to 18 which is maybe due to the size of a phosphate group, low penetration of the drug in cell membranes and dephosphorylation kinetics.77

The importance and structure–activity relationships of the 4′-hydroxy and 3′,5′-dimethyl substitution in the arylidene moiety and amino group in the 7-position were confirmed by designing appropriate derivatives (24 examples) and using them against Jurkat cells.78 A docking based study of various agents that bind to the colchicine site on tubulin was evaluated to get a seven point structure-based pharmacophore which is required for effective binding. The red, pink and yellow spheres (hydrogen bond acceptors; see Fig. 8) and blue sphere (hydrophobic center) mark the similar type of binding sites on the colchicine molecule as well as on indanocine 18.79 The overall geometric and steric requirements of binding with the colchicine molecule were satisfied by the rigid portion of the indanocine scaffold which is caused by the hydrophobic ring A and planar ring C (18 has six out of the seven-point pharmacophores).79 These results fortified the SAR derived earlier for indanocine derivatives.79 The theoretically calculated milog P and TPSA values for 18 and its 4-phosphate derivative 18a (see Table 3) corroborate well with the observed IC₅₀ values reinforcing the basic structural requirements. Based on these theoretical milog P calculations development of the monohydrochloride salt of 18 may have better cell penetration and bioavailability as observed for a millepachine derivative (see 22d in Fig. 11).77 At a concentration of 5 nM, 18 inhibited and strongly suppressed microtubule dynamics and resulted in concentration-dependent slow wound healing of MDA-MB-231 cells in the scratch wounds healing assay indicating a reduction in the migration of cells.76

The incorporation of indole motif as bioisostere for the dimethoxyaniline group of 18 provided with indole indanone derivative called indolocine 18b (Fig. 8), among 8 other derivatives studied as tubulin interacting agents.77 Indolocine 18b tested positive against the Non-Small Cell Lung NCI-H522 cell line in a nanomolar concentration. Retention of the 4′-hydroxy and 3′,5′-dimethyl substitution in the arylidene moiety of the new indolocine derivatives indicated that most derivatives were equipotent, and complemented the previous SAR73 as well as a pharmacophoric model.74 A striking resemblance to the 7-amine substitution from 18 is seen by incorporation of natural motifs like indole into the indanone structure like dilemmaones A–C (see red dashed box on structures) from South African sponge Ectyonanchora flabellata.78

3.1 Potential of tri-methoxy substitution on the indanone core for inhibiting cancer cell growth via tubulin interaction

The tri-methoxy benzene substituted moiety is common to several important tubulin binding natural molecules like colchicine, combretastatins-A4 and A-1 and podophyllotoxin (see Fig. 8 and 9), forming the hydrophobic center and interacting with the major binding site on tubulin.74 The red and pink spheres on combretatin A-4 and pink and yellow spheres on podophyllotoxin are hydrogen bond acceptors (Fig. 9) while the blue sphere (hydrophobic center) marks the similar type of binding sites seen on the colchicine molecule in tubulin by pharmacophore modeling.74 The incorporation of the 3,4,5-trimethoxyphenyl group found in ring A of colchicine into the ring A of indanone 19 and modification at the 3-position with another aryl ring having a tri-methoxy substitution pattern (see the E-ring in podophyllotoxin; Fig. 9) imparts anticancer properties to the indanone 19 scaffold against breast

---

**Fig. 8** Indanocine and its derivatives, colchicine as tubulin binding agents.
The introduction of the aryldiene moiety resulted in AIs of the type $19a$–$19c$ among the 15 derivatives tested against human cancer cell lines. Compounds $19a$, $19b$, and $19c$ were superior to the parent indanone, indicating an improvement in activity on the introduction of the arylidene moiety. Indanone $19b$ inhibited tubulin polymerization in the same range when compared to podophyllotoxin (see Table 3 for comparison of IC$_{50}$ values). Further in vivo acute oral toxicity tests in Swiss albino mice indicated 1000 mg kg$^{-1}$ body weight as a single acute oral dose. Indanone $19b$ showed antiproliferative activity against the ER$^+$ breast cancer cell line (MCF-7, IC$_{50}$ = 0.010 mM) and didn’t allow the cells to form colonies in a concentration-dependent manner. The in vivo oral toxicity test using $19b$ in Swiss albino mice indicated a 100 mg kg$^{-1}$ body weight dose once in 28 days as a single acute dose and a 300 mg kg$^{-1}$ body weight dose as a single dose.

Structurally the methylenedioxy group is an important moiety for cancer drug design which may interact favorably with the molecular targets in cancer cells and function as a prodrug by the action of cytochrome p450 enzymes. The 3,4-methylenedioxyphenyl moiety in polygamain (see Fig. 9), a natural product isolated from Amyris madrensis shares the same space occupied by the tri-methoxy benzene moiety found in podophyllotoxin and shows a hydrophobic interaction within the colchicine-binding site on tubulin. The presence of a fluorine atom in compound $19c$ shows better experimental potency in both tests, and plays a critical role in the design of several anti-cancer agents. Chalcone $19e$ having a similar substitution pattern with respect to the positioning of the fluorine and tri-methoxy groups had the highest potency (30 nM) towards inhibition of NO production in RAW macrophages.

Further development of the indanone scaffold ($7$ examples) with the introduction of the nitro group in the para-position gave $19d$ which has potent activity in several cancer cell lines and was tolerated up to 300 mg kg$^{-1}$ doses in acute oral toxicity experiments. In spite of $19d$ having an almost similar molar mass and calculated theoretical volume as $19b$, it violates Lipinski rule but was found to effectively cross the blood–brain barrier due to its lipophilic nature (milog$P$=4.52; Table 3).

Recently AI incorporating methoxy groups in the indanone core similar to the colchicine A-ring were evaluated in several human cancer cell lines as antitumor agents (18 examples). The studies showed that AI with 4,5,6-trimethoxyl substitution...
similar to the colchicine A-ring (20a–20b; Fig. 10) was more potent compared to the isomeric 5,6,7-trimethoxy, 5-methoxy-6-hydroxy and 5,6-dimethoxy indanone moieties tested.91 The synthetic aurone derivative 20c (an oxygen analog of active indanone 20a; Fig. 10) gave similar results against the K562 human chronic myelogenous leukemia cell line.92 It is worthwhile pointing out that the most active indanone derivative 20a shares the same tri-methoxy and isovanillin type substitution pattern as synthetic aurone and chalcone SD400 (ref. 92 and 93) (see Fig. 10 for structures and a comparison of the colored spheres with the binding sites seen on the colchicine molecule in tubulin by pharmacophore modelling74 in Fig. 8). Several trimethoxy substituted chalcones among others with diverse substitution patterns and the ability to inhibit tubulin have been reviewed.10

Incorporating medicinally important scaffolds like indoles94 with 4,5,6-trimethoxy indanones gave hybrid compounds with promising anti-cancer activity (14 examples). The linkage with the indole moiety was varied between the 3, 4 and 5 positions. The potent compounds (21a–21b and 22a–22b; Fig. 11) gave promising results in several cancer cell lines and inhibited tubulin with no influence of the position of contact with the indole moiety.95 Similarly, millepachine-indolyl chalcone 22c with substitution at the 5-position of N-methyl indole was the most potent among others and showed cytotoxicity against all tested cancer cells.96 The bioavailability of millepachine derivative 22d was improved by 47% after forming its hydrochloride salt.75 This rationale may also increase the bioavailability of derivative 20b which is a potent anti-tubulin agent, equipotent with 20a (see Fig. 10) and has structural similarity with the aryl ring in 22d.

Several chalcone derivatives attached to the 3-position of the indole ring have shown induction of methuosis, a non-apoptotic cell death,97 use as microtubule depolymerizing agents98,99 and have anti-inflammatory activities100 while when connected to the 5-position of indole ring function as imaging agents by competitively binding to the AB fibers for detection of β-amyloid plaques in the brains of AD patients.101

4. Therapeutic potential of AI against breast cancer

Aromatase is a cytochrome P450 enzyme, which functions as a rate-limiting enzyme in the conversion of androgens to estrogens. Nonsteroidal aromatase inhibitors of the type; 2-(4-pyridylmethylene)-1-indanone 23 (Fig. 12) showed selectivity and increased potency toward aromatase as compared to aminoglutethimide102,103. On similar lines, the relative potency of imidazolyl substituted derivative 24 against aromatase inhibition was 54 times more potent than aminoglutethimide (4 examples) and fared better in comparison with indanone 23. This potency may be attributed to the orientation of the side chain which influences the binding at the active site of aromatase.104 2-Benzylidene-4,7-dimethyl indan-1-one 25 showed inhibition against the MCF-7 cell line and was non-toxic to the normal breast cell line HBL-100 up to 100 μM.105 The 2-arylidene-1-indanones 25 and 26 (Fig. 12) were evaluated in MCF-7 cells showing superior activity (7.3 μM) in a dose-dependent manner.106

Fig. 12 Al and their derivatives inhibiting aromatase, MCF-7 cell growth and lung cancer.
5. Arylidene indanones in treatment of lung cancer

Akt activation and phosphorylation is the key to the survival of cancer cells and has been linked to lung cancer resistant to chemotherapy. The over-expression of Akt provides resistance to chemotherapy and makes it an interesting therapeutic tool for developing anti-cancer agents. Indan-1-one 25 inhibited Akt enzyme activity by 0.20 μM and did not alter the IC50 value on increasing the ATP concentration, indicating allosteric binding of the molecule to the enzyme. Indan-1-one 25 reduced cell proliferation of non-small cell lung cancer cell lines, NCI-H460 and A549 cells with a GI50 of 0.28 μM and 0.77 μM via the caspase-activated apoptosis pathway.107

6. Arylidene indanones in treatment of leukemia

The therapeutic effects of natural and synthetic flavonoids including chalcones with respect to structure activity relationships on various forms of leukemia has been recently reviewed.108 AIs being the rigid cousins of chalcones also play important roles in the therapy of leukemia. Indanocine 18 (Fig. 8) a potent tubulin binding agent, induces apoptosis in malignant B cells from patients with chronic lymphocytic leukemia (CLL) but remains ineffective in resistant CEM human lymphoblastoid cells due to a single point mutation of the nucleotide close to the colchicine binding site of tubulin.26 The combination of an equimolar concentration of 18, an anti-tubulin agent and mizoribine, a prodrug, synergistically led to a decrease in the viability of chronic lymphocytic leukemia (CLL) cells.109

7. Arylidene indanones as dual specificity phosphatase (DUSP) inhibitors

Dual specificity phosphatases (DUSP) are enzymes that dephosphorylate and inactivate mitogen-activated protein kinases (MAPKs). DUSP6, also known as mitogen-activated protein kinase phosphatase 3 (MKP3), functions as a feedback regulator of fibroblast growth factor (FGF) signaling to limit the activity of extracellular signal-regulated kinase (ERK) 1 and 2. The catalytic activity of members of the DUSP family like DUSP6 and DUSP1 is substrate specific which on interaction with ERK is enhanced, while DUSP5 is active and independent of substrate binding.28 FGFs play crucial roles in development, proliferation, and cellular homeostasis.28 These FGFs also bind to tyrosine kinase receptor proteins to activate the signaling of the rat sarcoma homolog RAS/MAPK cascade among others.118

BCI 27 was identified as a specific inhibitor of DUSP6 and DUSP1 but not of DUSP5 using a zebrafish chemical screen which is an animal model well suited for small molecule screening (Fig. 13).28,29 BCI 27 at a concentration of 10 μM, functions as an inhibitor of DUSP6 with increased expression of FGF in treated embryos. Furthermore, using analogs 27a and 27b it was shown that cyclohexylamine, as well as the benzylidene moiety, plays an important role in the inhibition (compare EC50 values in Table 4).28

A total of 11 compounds (from 29 examples) effectively activated FGF signaling in a concentration-dependent manner in Tg(dusp6:EGFP)29 embryos with most of them being as potent as the starting pharmacophore 27.29 Toxicity studies of the compounds indicated BCI analog 28a showed no toxicity even at twice the EC50 (20 μM) required for activation of FGF signaling indicating an attractive and clean molecule to investigate DUSPs.29 The theoretical milog P calculations (Table 4) provide results which would disqualify the active molecules 27 and 28a but substantiate the result for 28b, which follows the Lipinski “rule of five” with no violations. However, it is not a necessity to qualify the “rule of five” to have drug-likeness.111

The study revealed the more potent derivative 28b due to the introduction of a heteroatom in the ring at the 3-position of indanone and the fluoro substituent in 28c compared to 27.29 The importance of the carbonyl functionality was assayed by testing its reduced form as hydroxyl derivative 28d (Fig. 12), which showed no activity.29

The selective DUSP6 inhibitor, indanone 27, induced cell death in patient-derived pre-B acute lymphoblastic leukemia (ALL) cells and also overcome mechanisms of drug-resistance. Treatment of patient-derived ALL cells led to hyperactivation of Erk and compromised the negative control of Erk signaling causing cell death.112

8. Quinolinylmethyldiene indanones as antimalarial agents

Malaria is an infectious disease which causes deaths worldwide and is caused by transmission of Plasmodium strains by mosquito bites. Natural chalcones, like licochalcone A isolated from Chinese licorice roots protected mice infected with P. yoelii for 3 to 6 days.113 The quinoline moiety is important in drugs like chloroquine used for the treatment of malaria infections.114 Hybrids resulting from substituted indanones and quinolines led to indanones 29a and 29b (Fig. 14) as potent antimalarial agents (13 examples).29 SAR studies indicated that monosubstitution in the quinoline ring at position 8 were effective inhibitors of haem polymerization (29a and 29b). The in vivo tests using mice infected with Plasmodium berghei ANKA, showed survival up to 12 days after infection by treatment with indanone 29b (at a concentration of 20 mg kg−1 intraperitoneal once daily for 4 days post infection).29

The SAR was carried out by substitution in the indanone ring at positions 5 and 7 by a methoxy group as well as positions 6, 7 and 8 of the quinoline moiety (10 examples). In vivo tests in mice infected with Plasmodium berghei, showed a survival rate of 11 days for indanones 30a and 30b (at concentration of 20 mg kg−1 intraperitoneal once daily for 4 days post infection).31
9. Arylidene indanone as an aryl hydrocarbon receptor antagonist

Recently, the simple E/Z-2-benzylindene-5,6-dimethoxy-3,3-dimethylindan-1-one, 31 (Fig. 15) was shown to transiently act as an aryl hydrocarbon receptor (AhR) antagonist and selectively inhibit the UVB-induced expression of the CYP1A1 gene in normal human epidermal keratinocytes (NHEK). Results of the topical application of ointment containing 0.5% protected human skin from UV-B radiation by reduced expression of CYP1A1, COX-2 and MMP-1 genes.115

10. Bioavailability and SAR considerations

Although no bioavailability studies are reported for the AIs mentioned in this review, a concise description of the analysis, degradation and metabolism of acetylcholinesterase inhibitors i.e., donepezil, the most structurally related molecule to the AI scaffold has been reviewed.116 The current status of clinical trials using disease modifying drugs in AD has also been reviewed.117 The increased lipophilicity of 6-substituted derivatives 12b, 13a–13c which were equipotent to 6 (Table 1) may improve their bioavailability by delaying metabolic demethylation.116

Bioavailability of chalcone and arylidene indanone was shown to be dependent on the formation of ionized species of molecules (pKa) which have hydroxyl or N,N-dimethyl amino groups, which may inhibit their passive diffusion across cell membranes.118 The dimethylamino containing derivatives remain uncharged at pH 7.4; therefore, they may easily pass through the cellular membrane while the hydroxyl group may get ionized with the negative charge which may inhibit their diffusion. Inclusion complexes with cyclodextrins have shown great potential for drug delivery systems by increasing their bioavailability.119,120

Although, the 4'-phosphate derivative of indanocine showed reduced cytotoxicity compared to 18,72 the phosphate derivatives of combretastatin-like chalcones have functioned as prodrugs and were equipotent to the parent molecules with respect to cell proliferation. While the same compounds were inactive for tubulin inhibition probably due to the in vitro assay not being cell-based and no hydrolysis by phosphatases can occur.93

* EC50-concentration required for FGF activation in zebrafish assay; ND-not determined.
Several combretastatin analogs like A-1 and A-4 phosphates are in various stages of clinical trials.\textsuperscript{121} The ethoxy derivative had a better half-life compared to its methoxy derivative and also improved the potency by delaying possible metabolic inactivation.\textsuperscript{122} The lipophilic acetate derivative of the natural flavonoid quercetin increased uptake in cells and delayed metabolism.\textsuperscript{123} Inhibition of P-glycoprotein (P-gp), the drug efflux transporter in cancer cells can help increase the bioavailability of anti-cancer drugs. Natural flavonoids have been shown to be inhibitors of P-gp and have been co-administered with anti-cancer drugs.\textsuperscript{108} Indanone derivatives like 32a and 32b have shown inhibition activity in the nanomolar range towards efflux of daunomycin using the CCRF vcr1000 cell line (Fig. 15).\textsuperscript{124} The SAR provides insights into the higher activity of 32b based on the presence of one more rotatable bond than 32a while the remaining structure is identical.\textsuperscript{124} Indanones 33a–33e have shown modulation of the ABCG2 transporter which is responsible for the efflux of a wide variety of drugs resulting in drug resistance.\textsuperscript{125,126} The resulting SAR indicated the presence of the dimethoxylated A-ring, adjacent to the carbonyl group and the exocyclic double bond to be key features for such activity. The activity was also dependent on the mono or disubstituted aryl ring having hydroxyl or methoxyl groups (33b–33e).\textsuperscript{125} The majority of publications discussed in this review have a substitution at the para position of the arylidene ring, with ortho positions effectively not explored. The substitution of an ortho position, in comparison to the para isomer, can be differentiated by ESI-MS in AI as well as chalcones.\textsuperscript{23,127} Moreover the o-substituted chalcone derivative has higher potency compared to p-substituted when the other structural substitutions are maintained.\textsuperscript{84,128} The ring B of flavopiridol and combretastatin A-1 are classical examples of ortho substituents influencing the potential of these scaffolds as therapeutic drugs.\textsuperscript{121} The potency of combretastatin derivatives having a 2-amino substitution in the B-ring was improved as inhibitors of tubulin assembly, cytotoxicity and in vivo reduction of blood flow to tumors.\textsuperscript{129}

Incorporation of the N-methyl-piperidinyl alkaloid moiety found in flavopiridol without the hydroxyl group in chalcones 34 has shown anti-cancer properties by inhibiting cell cycle progression\textsuperscript{11,130} and can be explored on the AI scaffold. Incorporation of indole or quinoline moieties with indanone may be beneficial in the design of new antimicrobial or antimalarial agents,\textsuperscript{114} which may become more effective for resistant strains of bacteria on quaternization of nitrogen and improved solubility in the physiological medium.\textsuperscript{131}

11. Conclusions

Arylidene indanones tested as acetylcholinesterase inhibitors have shown that the 6-position of the indanone core is important for interactions with the PAS of the enzyme\textsuperscript{45} and subsequent modifications improve the efficiency of interaction.\textsuperscript{45,49,51} Chelation of metals like copper is critical for Alzheimer’s therapy and chelating groups like piperidinyl ethoxy mimicking clioquinol in 12b or the catechol moiety in 16a serve as an

**Fig. 14** Quinolinylmethylidene indanones and licochalcone A as antimalarial agents.

**Fig. 15** Aryl hydrocarbon Receptor (AhR) antagonist, P-glycoprotein and ABCG2 inhibitors based on AI; flavopiridol and its chalcone derivative as inhibitors of cell cycle progression.
important aspect for new drug design.\textsuperscript{27-29} Incorporation of bulky groups like bis(4-fluoroaryl)methyl on piperazine either on the indanone side \textbf{11c} or arylidene ring \textbf{14a} can modulate either as a BACE1 inhibitor or acetylcholinesterase inhibitor.\textsuperscript{46-48} Tubulin depolymerization agents require the tri- methoxy substitution on the indanone ring to mimic the colchicine type activity.\textsuperscript{74,80,81,91,95}

Tunability of the \(\alpha,\beta\)-unsaturated ketone system as a Michael acceptor is paramount to the type of biological activity,\textsuperscript{11,12} since these systems are present in many natural products like chalcones as well as AIs, where the molecule is more planar comparatively and the transmission of electronic effects of the aryl substituents are directed towards the carbonyl group.\textsuperscript{13} The importance of the double bond at the 2-position in arylidene indanone has been verified by SAR studies, indicating no DUSP inhibition activity if removed\textsuperscript{28} or improved tubulin activity compared to unsubstituted compounds\textsuperscript{79-81} or diminished AChE activity if removed or hydrogenated.\textsuperscript{49,52} Similarly increased MAO-B inhibition was seen for benzylidene substituted 5-hydroxyindanones.\textsuperscript{61,63}

The chalcones have been merited with a lot of attention by structural modification of the position of the hydroxyl, methoxyl and other substitutions such as incorporation of heteroaryl moieties like coumarins, naphthyl, furan etc. displaying diverse activities.\textsuperscript{10-12} Similarly, in-depth studies of novel arylidene indanone scaffolds by pharmacophore modeling may give better insights into the unexplored potential of this scaffold.
