Group 3 metal trihalide complexes with neutral N-donor ligands – exploring their affinity towards fluoride†

Emily Curnock,^a William Levason,^b Mark E. Light,^a Sajinder K. Luthra,^b Graeme McRobbie,^b Francesco M. Monzittu,^a Gillian Reid^{*a} and R. Nathan Williams^a

Fluorination of [ScCl₃(Me₃-tacn)] (Me₃-tacn = 1,4,7-trimethyl-1,4,7-triazacyclononane) and [ScCl₃(BnMe₂-tacn)] (BnMe₂-tacn = 1,4-dimethyl-7-benzyl-1,4,7-triazacyclononane) by Cl/F exchange with 3 mol. equiv. of anhydrous [NMe₄]F in CH₃CN solution yields the corresponding [ScF₃(R₃-tacn)] (R₃ = Me₃ or BnMe₂). These are the first examples of scandium fluoride complexes containing neutral co-ligands. The fluorination occurs stepwise, and using a deficit of [NMe₄]F produced [ScF₂Cl(Me₃-tacn)]. Attempts to fluorinate [YCl₃(Me₃-tacn)], [YI₃(Me₃-tacn)], [LaCl₃(Me₃-tacn)(OH₂)] or [MCl₃(terpy)] (M = Sc, Y or La; terpy = 2,2':6'2''-terpyridyl) using a similar method were unsuccessful, due to the Cl/F exchange being accompanied by loss of the neutral ligand from the metal centre. Fluorination of [ScCl₃(Me₃-tacn)] or [ScCl₃(terpy)] with Me₃SnF was also successful. The products were identified as the very unusual heterobimetallic [Sc(Me₃-tacn)F₂(μ-F)SnMe₃Cl] and [Sc(terpy)F(μ-F)₂(SnMe₃Cl)₂], in which the Me₃SnCl formed in the reaction behaves as a weak Lewis acid towards the scandium fluoride complex, linked by Sc–F–Sn bridges. [Sc(terpy)F(μ-F)₂(SnMe₃Cl)₂] decomposes irreversibly in solution but, whilst multinuclear NMR data show that [Sc(Me₃-tacn)F₂(μ-F)SnMe₃Cl] is dissociated into the [ScF₃(Me₃-tacn)] and Me₃SnCl in CH₃CN solution, the bimetallic complex reforms upon evaporation of the solvent. The new scandium fluoride complexes and the chloride precursors have been characterised by microanalysis, IR and multinuclear NMR (¹H, ¹⁹F, ⁴⁵Sc) spectroscopy as appropriate. X-ray crystal structures provide unambiguous evidence for the identities of [Sc(Me₃-tacn)F₂(μ-F)SnMe₃Cl], [ScF₂Cl(Me₃-tacn)], [YI₃(Me₃-tacn)], [(YI₂(Me₃-tacn))₂(μ-O)], [ScCl₃(terpy)], [YCl₃(terpy)(OH₂)], and [(La(terpy)(OH₂)Cl₂)₂(μ-Cl)₂]. Once formed, the [ScF₃(R₃-tacn)] complexes are stable in water and unaffected by a ten-fold excess of Cl[−] or MeCO₂[−], although they are immediately decomposed by excess F[−]. The potential use of [ScF₃(R₃-tacn)] type complexes as platforms for ¹⁸F PET (positron emission tomography) radiopharmaceuticals is briefly discussed. Attempts to use the Group 3 fluoride “hydrates”, MF₃·xH₂O, as precursors were unsuccessful; no reaction with R₃-tacn or terpy occurred either on reflux in CH₃CN or under hydrothermal conditions (H₂O, 180 °C, 15 h). PXRD data showed that these “hydrates” actually contain the anhydrous metal trifluorides with small amounts of surface or interstitial water.

Introduction

The coordination chemistries of scandium and yttrium have been explored much less than those of the other 3d and 4d

metals. The presence of colourless metal ions, in a single (3+) oxidation state and with closed shell configurations (hence no magnetic or d–d spectroscopic fingerprints), coupled with their limited availability, low purity and high cost, restricted early work.^{1,2} Often their chemistry was included in studies of the lanthanide elements, which tended to see similarities rather than explore differences.² More recent work³ has shown that there are significant differences, especially for scandium, and the structural chemistry of scandium is surprisingly diverse.⁴ A rich, but synthetically challenging, organometallic chemistry of both metals has been explored in recent years,⁵ and C–H bond activation, ethene, styrene and α-olefin polymerisation, and aromatic C–F bond activation have all been

†Electronic supplementary information (ESI) available: X-ray crystallographic parameters are given in Table S1. The ESI also contains IR and NMR spectra for the complexes and figures showing the π-stacking and H-bonding in the terpy complexes. CCDC 1590538–1590545. For ESI and crystallographic data in CIF or other electronic format see DOI: 10.1039/c8dt00480c

observed in appropriate systems.^{5–9} Scandium fluoride has attracted considerable interest due to its negative thermal expansion,¹⁰ and nanocrystals of ScF₃ doped with lanthanide ions exhibit tuneable luminescent properties.¹¹ As expected for oxophilic metal ions, the coordination chemistry with neutral ligands has been dominated by oxoanion salts – nitrate, triflate, carboxylates, *etc.*, with much less work on the metal halides.³ Apart from a range of fluoro-anions mostly made by solid state syntheses,^{2,12} complexes containing Sc–F or Y–F bonds are very rare and contain charged N- or C-donor coligands,⁴ *e.g.* [ScL(μ-F)₂(SnMe₃Br)₂] (L[–] = N,N'-(1,3-dimethyl-1,3-propanediylidene)bis(N',N'-diethyl-1,2-ethanediamine)) made from [ScLBr₂] and Me₃SnF,¹³ [Sc{MeC(N(2,6-¹PrC₆H₃))-CHC(Me)(NCH₂CH₂NMe)NH(2,6-¹PrC₆H₃)}F],⁶ [Sc₂(μ-F)₂{Fe(C₅H₄NSi^{*i*}BuMe₂)₂}]₂,⁹ [(Cp₂Y(μ-F)(thf)₂)₂],⁸ and [(Cp₂ScF)₃].¹⁴ Attempts to prepare complexes of ScF₃ or YF₃ with neutral donor ligands,¹⁵ such as R₃PO,¹⁶ have failed, whilst treatment of [ScI₃{*o*-C₆H₄(PMe₂)₂}] with [NMe₄]F in CH₂Cl₂ resulted in liberation of the diphosphine and precipitation of ScF₃.¹⁷

In an effort to develop new PET (positron emission tomography) imaging agents, the ability of Group 13 metal (Al, Ga or In) aza-macrocycle complexes to undergo Cl/F exchange, including in some cases with radiofluorine, ¹⁸F, under mild conditions and in aqueous solution has been demonstrated.¹⁸ These include both the neutral trifluoride complexes, [MF₃(R₃-tacn)] (M = Al, Ga; R₃-tacn = 1,4,7-trimethyl-1,4,7-triazacyclononane, 1,4-dimethyl-7-benzyl-1,4,7-triazacyclononane)¹⁹ and anionic complexes, [M(nota)F] (H₂-R-nota = 1-R-1,4,7-triazacyclononane-4,7-dicarboxylic acid; R = benzyl or a peptide conjugate).^{20,21} The ideal requirements for PET imaging agents are that the metal complex precursor can be rapidly radiofluorinated in a single step, with minimal subsequent purification needed, and that the resulting complex is stable in water, to reaction with other competitive anions and at near neutral pH. The present work sought to establish whether Group 3 metal centres (Sc, Y or La) could offer prospects as alternative reagents for radiofluorination as potential future PET platforms and therefore explores the synthesis, properties and stability of the metal trifluoride complexes with tridentate neutral N₃-donor ligands, R₃-tacn and 2,2':6'2"-terpyridyl.

Experimental

All complex syntheses were carried out using standard Schlenk and vacuum line techniques. Samples were handled and stored in a glove box under a dry dinitrogen atmosphere to exclude moisture, which decomposes many of the samples. [ScCl₃(thf)₃] and [YCl₂(thf)₅][YCl₄(thf)₂] were prepared by the literature methods.^{22,23} 2,2':6'2"-terpyridyl was obtained from Sigma-Aldrich and dried *in vacuo* prior to use. 1,4,7-Trimethyl-1,4,7-triazacyclononane and 1,4-dimethyl-7-benzyl-1,4,7-triazacyclononane were prepared as described previously.²⁴ Anhydrous [NMe₄]F was obtained by recrystallising the commercial sample (Aldrich) from ¹PrOH as described.²⁵ Infrared spectra were recorded as Nujol mulls between CsI plates using

a PerkinElmer Spectrum 100 spectrometer over the range 4000–200 cm^{–1}. ¹H, ¹⁹F{¹H} and ⁴⁵Sc NMR spectra were recorded from CH₂Cl₂/CD₂Cl₂ or CH₃CN/CD₃CN solutions using a Bruker AV400 spectrometer and referenced to TMS *via* the residual solvent resonance, CFCl₃ and [Sc(H₂O)₇]³⁺ in water at pH = 1. Microanalyses were undertaken by London Metropolitan University. *n*-Hexane was dried by distillation from sodium and CH₂Cl₂ and CH₃CN from CaH₂.

Metal trifluoride “hydrates”

ScF₃·xH₂O. Sc₂O₃ (2.9 g, 0.021 mol), and a 6 M solution of HCl (43 mL) were heated to reflux for 3 h, during which period the mixture changed from a cloudy white suspension to a clear yellow solution. The solvent was removed *in vacuo* whilst heating at 65 °C. ScCl₃·6H₂O was obtained as a white solid. This was dissolved in water in a plastic beaker and 6 mL of 40% HF_(aq) (CARE) were added causing the precipitation of a white solid. The mixture was heated to boiling and the solvent evaporated, giving a white gel-like solid. A portion of the gel was suspended in water, causing the formation of the solid, which was isolated by evaporation of the solvent. The same procedure was repeated portion by portion and the solid combined (3.94 g, 93%).

YF₃·xH₂O. *Method 1:* Y₂(SO₄)₃·8H₂O (3.0 g, 4.92 mmol) was dissolved in water. 5 mL of a solution of 40% HF_(aq) was added and a white precipitate formed. The precipitate was left to settle overnight. The solution was filtered and the solid washed with water and dried *in vacuo* (1.07 g, 75%).

Method 2: Y₂(SO₄)₃·8H₂O (3.0 g, 4.92 mmol) was suspended in hot water (80 °C) until most of the solid dissolved. The liquid was decanted off from any residue and a solution of 40% HF_(aq) (3 mL) was added to the solution. A white solid precipitated immediately. The reaction was left stirring for 1.5 h and then the solid was left to settle overnight. The solution was decanted off and the solid dried overnight in a desiccator (1.24 g, 86%).

LaF₃·xH₂O. LaCl₃·7H₂O (5.0 g, 13.5 mmol) was dissolved in water (30 mL). 40% HF_(aq) (1.5 mL) was diluted in water (10 mL) and added dropwise to the solution, giving a white gelatinous material which was stirred for 1 h. This solid was collected by evaporating the solvent off at 110 °C, leaving a fine white solid. Yield: 2.50 g, 95%.

Metal complexes

[ScCl₃(terpy)]. A solution of terpy (0.055 g, 0.24 mmol) in 3 mL of CH₃CN was added to a solution of [ScCl₃(thf)₃] (0.076 g, 0.24 mmol) in 5 mL of CH₃CN, causing the immediate precipitation of a white solid. After a few minutes, the solid was filtered off, washed with *n*-hexane and dried *in vacuo*. Yield: 0.054 g, 60%. Required for C₁₅H₁₁Cl₃N₃Sc: C, 46.8; H, 2.9; N, 10.9. Found: C, 46.7; H, 3.1; N, 11.1%. ¹H NMR (CD₂Cl₂, 298 K): δ = 9.25 (m, [2H], Ar), 8.30 (m, [7H], Ar), 7.80 (s, [2H], Ar). ⁴⁵Sc NMR (CD₂Cl₂, 298 K): δ = 254 (s, br). IR (Nujol, ν/cm^{–1}): 292, 339, 337 (Sc–Cl). Colourless crystals were obtained from slow diffusion of Et₂O into a concentrated solution of the complex in CH₃CN.

[YCl₃(terpy)(OH₂)]. A solution of terpy (0.046 g, 0.20 mmol) was added to a solution of [YCl₂(thf)₅][YCl₄(thf)₂] (0.08 g, 0.09 mmol) in anhydrous CH₃CN, causing the immediate precipitation of a white solid. After 30 minutes, the white solid was filtered, washed with *n*-hexane and dried *in vacuo*. Yield: 0.051 g, 61%. Required for C₁₅H₁₃Cl₃N₃OY: C, 40.3; H, 2.9; N, 9.4. Found: C, 40.2; H, 3.0; N, 9.5%. ¹H NMR (CD₃CN, 298 K): δ = 9.84 (m, [2H], Ar), 8.48 (m, [2H], Ar), 8.39 (m, [3H], Ar), 8.17 (td, [2H], Ar), 7.69 (t, [2H], Ar), 2.15 (s, H₂O). IR (Nujol, ν/cm⁻¹): 3338, 1641 (H₂O), 272, 262(sh) (Y–Cl). Colourless crystals were grown by placing the Schlenk tube containing the filtrate in the freezer (–18 °C) for a few days.

[LaCl₃(terpy)(OH₂)·4H₂O]. LaCl₃·7H₂O (0.108 g, 0.44 mmol) was dissolved in ethanol (10 mL). Terpy (0.098 g, 0.42 mmol) was suspended in ethanol (10 mL) and the reagents combined. A white precipitate formed, which was stirred for 45 min. The solvent was then removed by filtration and the solid washed with ethanol, then diethyl ether and dried *in vacuo*. Yield: 0.09 g, 40%. Required for C₁₅H₂₁Cl₃LaN₃O₅: C, 31.7; H, 3.7; N, 7.4. Found: C, 31.8; H, 4.0; N, 6.9%. ¹H NMR (CD₃OD, 298 K): δ = 9.37 (m, br, [2H], Ar), 8.59 (m, br, [3H], Ar), 8.40 (m, br, [2H], Ar), 8.27 (m, br, [2H], Ar), 7.77 (m, br, [2H], Ar), 4.85 (H₂O). IR (Nujol, ν/cm⁻¹): 3369, 1633 (H₂O), 209, 205 (La–Cl). Colourless crystals of [{La(terpy)(OH₂)Cl₂]₂(μ–Cl)₂] were obtained by layering an ethanol solution of LaCl₃·7H₂O with an equimolar solution of terpy in ethanol, and leaving undisturbed for 48 h.

[LuCl₃(terpy)(OH₂)]. LuCl₃·6H₂O (0.113 g, 0.29 mmol) was dissolved in ethanol (10 mL). Terpy (0.069 g, 0.30 mmol) was dissolved in ethanol (5 mL) and added dropwise. After stirring for 2 h, a white precipitate had formed. The precipitate was collected *via* filtration, washed with diethyl ether (2 mL) and then dried in a desiccator for one hour, leaving a white powder. Yield: 0.120 g, 77%. Required for C₁₅H₁₃Cl₃LuN₃O: C, 33.8; H, 2.5; N, 7.9. Found: C, 33.7; H, 2.5; N, 7.7%. ¹H NMR (CD₃OD, 298 K): δ = 9.41 (d, [2H], Ar), 8.72 (d, [2H], Ar), 8.67 (m, [3H], Ar), 8.51 (t, [2H], Ar), 8.35 (t, [2H], Ar). IR (Nujol, ν/cm⁻¹): 3424, 1657 (H₂O) 205, 201 (Lu–Cl). Colourless crystals of [LuCl₃(terpy)(OH₂)] were grown by layering an ethanol solution of LuCl₃·6H₂O with an equimolar solution of terpy in ethanol, and leaving undisturbed for one week.

[ScCl₃(Me₃-tacn)]. [ScCl₃(Me₃-tacn)] was prepared by the literature method.²⁶ Required for C₉H₂₁Cl₃N₃Sc: C, 33.5; H, 6.6; N, 13.0. Found: C, 33.5; H, 6.7; N, 13.2%. ¹H NMR (CD₃CN, 298 K): δ = 3.22 (m, [6H], CH₂), 2.93 (m, [6H], CH₂), 2.87 (s, [9H], CH₃). ⁴⁵Sc NMR (CD₃CN, 298 K): δ = 300 (s). IR (Nujol, ν/cm⁻¹): 353, 330 (Sc–Cl).

[ScCl₃(BnMe₂-tacn)]. [ScCl₃(thf)₃] (0.066 g, 0.2 mmol) was dissolved in acetonitrile (10 mL). A solution of BnMe₂-tacn (0.051 g, 0.2 mmol) in acetonitrile (5 mL) was then added. The reaction was left stirring for 3 h and the solvent was removed *in vacuo* giving an off-white solid, which was washed with hexane and dried *in vacuo*. Yield: 0.079 g, 57%. Required for C₁₅H₃₁Cl₃N₃Sc: C, 45.2; H, 6.3; N, 10.5. Found: C, 45.3; H, 6.5; N, 10.7%. ¹H NMR (CD₃CN, 298 K): δ = 7.35 (m, [5H], Ar), 3.82 (s, [2H], N–CH₂–Ar), 2.98 (s, [4H], CH₂), 2.77 (m, [8H], CH₂),

2.50 (s, [6H], CH₃). ⁴⁵Sc NMR (CD₃CN, 298 K) δ = 302 (s). IR (Nujol, ν/cm⁻¹): 333, 301 (br, Sc–Cl).

[YCl₃(Me₃-tacn)]. [YCl₃(Me₃-tacn)] was prepared by the literature method.²⁶ Required for C₉H₂₁Cl₃N₃Y: C, 29.5; H, 5.8; N, 11.5. Found: C, 29.8; H, 5.9; N, 11.3%. ¹H NMR (CD₃CN, 298 K): δ = 3.12 (m, [6H], CH₂), 2.91 (m, [6H], CH₂), 2.82 (s, [9H], CH₃). IR (Nujol, ν/cm⁻¹): 323, 289 (Y–Cl).

[YI₃(Me₃-tacn)]·1.5CH₃CN. YI₃ (0.122 g, 0.26 mmol) was suspended in acetonitrile (10 mL). A solution of Me₃-tacn (0.044 g, 0.26 mmol) in acetonitrile (10 mL) was added. The reaction mixture was heated to 40 °C until a clear solution was obtained. After cooling, the volatiles were reduced *in vacuo* to 5 mL causing the precipitation of a white solid, which was filtered and dried *in vacuo* (0.078 g, 47%). Required for C₉H₂₁I₃N₃Y·1.5CH₃CN: C, 20.5; H, 3.7; N, 9.0. Found: C, 21.2; H, 3.9; N, 8.4%. ¹H NMR (CD₃CN, 298 K): δ = 3.46 (m, [6H], CH₂), 3.12 (s, [9H], CH₃), 2.92 (m, [6H], CH₂), 1.98 (s, CH₃CN). IR (Nujol, ν/cm⁻¹): 2253, 2187 (CH₃CN). Crystals suitable for single crystal X-ray analysis were obtained from a separate reaction by placing the Schlenk flask in the freezer (–18 °C). After a few days, two different crystal morphologies were found, which were identified by single crystal X-ray diffraction to be [YI₃(Me₃-tacn)]·CH₃CN and [YI₂(Me₃-tacn)]₂(μ–O)], the latter formed *via* hydrolysis from trace water ingress into the flask during crystallisation in the freezer.

[LaCl₃(Me₃-tacn)(OH₂)]. LaCl₃·7H₂O (0.101 g, 0.41 mmol) was dissolved in ethanol (10 mL). Me₃-tacn (0.06 mL, 0.41 mmol) in ethanol (5 mL) was added to form a white precipitate. After stirring for 45 min, the solvent was removed *in vacuo* leaving a white sticky solid which was dried in a desiccator for two hours. The solid was then washed with diethyl ether (3 mL) and dried again *in vacuo*, leaving a white powder. Yield: 0.09 g, 54%. Required for C₉H₂₃Cl₃LaN₃O: C, 24.9; H, 5.3; N, 9.7. Found: C, 25.6; H, 5.2; N, 10.0%. ¹H NMR (CD₃CN, 298 K): δ = 2.83 (m, [12H], CH₂), 2.57 (s, [9H], CH₃), 2.10 (H₂O). ¹H NMR (CD₃OD, 178 K): δ = 3.30 (H₂O), 2.92 (m, [6H], CH₂), 2.77 (m, [6H], CH₂), 2.62 (s, [9H], CH₃). IR (Nujol, ν/cm⁻¹): 3376, 1635 (H₂O), 207 (La–Cl).

[Sc(terpy)F(μ–F)₂(SnMe₃Cl)₂]. [ScCl₃(terpy)] (0.05 g, 0.13 mmol) was suspended in CH₃CN (8 mL) and a suspension of Me₃SnF (0.083 g, 0.45 mmol) in CH₃CN (15 mL) was added. After one hour most of the solid had dissolved. The mixture was left stirring for 6 hours. The liquid was decanted *via* cannula and the solvent removed *in vacuo*, giving a slightly pink solid. The solid was washed with hexane and dried *in vacuo* (0.031 g, 33%). Required for C₂₁H₂₉Cl₂F₃N₃ScSn₂: C, 34.4; H, 4.0; N, 5.7. Found: C, 34.8; H, 3.9; N, 6.9%. ¹H NMR (CD₃CN, 298 K): δ = 8.68 (br, [2H], Ar–CH₂), 8.48 (br, [3H], Ar–CH₂), 8.05 (br, [2H], Ar–CH₂), 7.95 (br, [2H], Ar–CH₂), 7.45 (br, [2H], Ar–CH₂), 0.60 (s, ²J_{SnH} = 64 Hz, Me₃SnCl). ¹⁹F{¹H} NMR (CD₃CN, 298 K): δ = –37.7 (br s, [2F]), –53.3 (br s, [F]). ⁴⁵Sc NMR (CD₃CN, 298 K): δ = 64 (s, br). IR (Nujol, ν/cm⁻¹): 489, 509, 544 (Sc–F), 270 (Sn–Cl).

[ScF₃(Me₃-tacn)]. [ScCl₃(Me₃-tacn)] (0.05 g, 0.15 mmol) was dissolved in acetonitrile (10 mL). [NMe₄]F (0.046 g, 0.46 mmol) was suspended in CH₃CN (10 mL) and added dropwise to the

solution of the complex. The reaction was left stirring for 90 minutes. Some white solid was evident throughout the reaction. The volatiles were removed *in vacuo* and the resulting white solid was washed with CH_2Cl_2 , filtered and dried *in vacuo* (0.041 g, 97%). Required for $\text{C}_9\text{H}_{21}\text{F}_3\text{N}_3\text{Sc}\cdot\text{NMe}_4\text{Cl}$: C, 40.8; H, 8.7; N, 14.6. Found: C, 41.7; H, 9.2; N, 14.6%. ^1H NMR (CD_3CN , 298 K): δ = 3.16 (s, [12H], NMe_4Cl), 2.85 (s, [9H], CH_3), 2.72–2.87 (m, [12H], CH_2). $^{19}\text{F}\{^1\text{H}\}$ NMR (CD_3CN , 298 K): δ = 8.2 (m, [$\text{ScF}_3(\text{Me}_3\text{-tacz})$]). ^{45}Sc NMR (CD_3CN , 298 K): δ = 104 (quartet, [$\text{ScF}_3(\text{Me}_3\text{-tacz})$]), $^1J_{\text{ScF}}$ = 215 Hz). IR (Nujol, ν/cm^{-1}): 579, 546 (Sc–F).

[Sc(Me₃-tacz)F₂(μ -F)SnMe₃Cl]. Me_3SnF was ground and dried under vacuum for 30 min. [$\text{ScCl}_3(\text{Me}_3\text{-tacz})$] (0.066 g, 0.20 mmol) dissolved in CH_3CN (10 mL) was added to a solution of Me_3SnF (0.133 g, 0.72 mmol), giving a clear solution in 20 min. The reaction mixture was stirred for 4 h. The solvent was then removed *in vacuo* and the white solid was dissolved in CH_2Cl_2 (5 mL). Hexane was added causing the precipitation of a white solid, which was filtered and dried *in vacuo* (0.078 g, 81%). Required for $\text{C}_{12}\text{H}_{30}\text{ClF}_3\text{N}_3\text{O}_3\text{ScSn}$: C, 30.5; H, 6.4; N, 8.9. Found: C, 30.3; H, 6.5; N, 8.8%. ^1H NMR (CD_3CN , 298 K): δ = 2.72–2.87 (m, [12H], CH_2), 2.61 (s, [9H], CH_3), 0.60 (s, [9H], Me_3SnCl). $^{19}\text{F}\{^1\text{H}\}$ NMR (CD_3CN , 298 K): δ = 7.7 (m). ^{45}Sc NMR (CD_3CN , 298 K): δ = 104 (q, $^1J_{\text{ScF}}$ = 227 Hz). IR (Nujol, ν/cm^{-1}): 556, 547 (Sc–F), 269 (Sn–Cl). Crystals of [$\text{Sc}(\text{Me}_3\text{-tacz})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}$] were obtained from slow evaporation of a concentrated solution of the product in CH_3CN .

[ScF₃(BnMe₂-tacz)]. A suspension of [NMe_4]F (0.027 g, 0.38 mmol) in CH_3CN (5 mL) was added to a suspension of [$\text{ScCl}_3(\text{BnMe}_2\text{-tacz})$] (0.038 g, 0.13 mmol) in CH_3CN (10 mL). The white precipitate present in solution was removed by filtration. The filtrate was taken to dryness *in vacuo* giving a light yellow solid (0.010 g, 57%). ^1H NMR (CD_3CN , 298 K): δ = 7.35 (m, [5H], Ar) 3.82 (s, [2H], N– CH_2 –Ar), 3.16 (s, [12H], NMe_4Cl), 2.98 (s, [4H], CH_2), 2.77 (m, [8H], CH_2), 2.50 (s, [6H], CH_3). $^{19}\text{F}\{^1\text{H}\}$ NMR (CD_3CN , 298 K): δ = 10.1 (br). ^{45}Sc NMR (CD_3CN , 298 K): δ = 104 (br).

X-ray experimental

Crystals of the complexes were grown as reported in the Experimental section. Data collections used a Rigaku AFC12 goniometer equipped with an enhanced sensitivity (HG) Saturn724+ detector mounted at the window of an FR-E+ SuperBright molybdenum (λ = 0.71073 Å) rotating anode generator with VHF Varimax optics (70 micron focus) with the crystal held at 100 K. Structure solution and refinement were performed using SHELXL(S/L)97, SHELX-2013 or SHELX-2014/7.²⁷ H atoms bonded to C were placed in calculated positions using the default C–H distance, and refined using a riding model. Details of the crystallographic parameters are given in Table S1.† CCDC reference numbers in cif format are [$\text{ScCl}_3(\text{terpy})$]: 1590538, [$\text{YCl}_3(\text{terpy})(\text{OH}_2)$]: 1590539, [$\text{ScF}_2\text{Cl}(\text{Me}_3\text{-tacz})$]: 1590540, [$\text{YI}_3(\text{Me}_3\text{-tacz})$]- CH_3CN : 1590541, [$\text{YI}_2(\text{Me}_3\text{-tacz})_2(\mu\text{-O})$]- CH_3CN : 1590542, [$\text{La}(\text{terpy})(\text{OH}_2)\text{Cl}_2$]₂($\mu\text{-Cl}$)₂: 1590543, [$\text{Sc}(\text{Me}_3\text{-tacz})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}$]: 1590544, [$\text{LuCl}_3(\text{terpy})(\text{OH}_2)$]: 1590545.† Powder X-ray diffraction data

were collected on a Bruker D2 diffractometer using Cu K α X-rays and refined using the GSAS software.²⁸

Results and discussion

Three possible routes to Group 3 metal trifluoride complexes of R₃-tacz and terpy (L) were considered:

- (1) Direct reaction with the “hydrated” Group 3 metal trifluorides with the neutral ligands;
- (2) Chloride(iodide)/fluoride exchange by reaction of the pre-formed Group 3 metal trichloride or triiodide complexes, [$\text{MX}_3(\text{L})$] (X = Cl or I), with anhydrous [NMe_4]F;
- (3) Chloride(iodide)/fluoride exchange by reaction of the pre-formed Group 3 metal trichloride or triiodide complexes, [$\text{MX}_3(\text{L})$] (X = Cl or I), with Me_3SnF .

Attempted synthesis from $\text{MF}_3\cdot x\text{H}_2\text{O}$ (M = Sc, Y, La)

The anhydrous Group 3 metal fluorides, MF_3 , are inert, polymeric solids and unreactive towards neutral ligands.^{1,15} Whilst the anhydrous Group 13 metal fluorides, MF_3 (M = Al, Ga, In) are similarly inert, the hydrates $\text{MF}_3\cdot 3\text{H}_2\text{O}$ are more reactive; they can be reacted with neutral ligands to form metal trifluoride ligand complexes, [$\text{MF}_3(\text{L})$] $\cdot x\text{H}_2\text{O}$, most easily under hydrothermal conditions (180 °C).^{19,29,30} Therefore, we postulated that it may be possible to use the Group 3 metal fluoride hydrates [$\text{MF}_3\cdot x\text{H}_2\text{O}$] (M = Sc, Y, La) to form analogous metal trifluoride ligand complexes. Literature data on the hydrates is sparse and the amount of water present apparently variable, although “x” typically appears to be less than one.

The addition of a fluoride source, either KF or aqueous HF, to aqueous solutions of yttrium or lanthanum salts, gave immediate white precipitates, $\text{MF}_3\cdot x\text{H}_2\text{O}$. Using scandium salts and aqueous HF also gave $\text{ScF}_3\cdot x\text{H}_2\text{O}$, but using alkali metal fluorides gave mixtures, and in one case pure KSc_2F_7 , which was identified by its PXRD pattern (see ESI†). The PXRD patterns obtained from $\text{MF}_3\cdot x\text{H}_2\text{O}$ sometimes showed rather broad reflections, but corresponded to the patterns reported for *anhydrous* MF_3 (Fig. 1 and ESI†).

Thus, we conclude that the $\text{MF}_3\cdot x\text{H}_2\text{O}$ actually comprise of the “*anhydrous*” MF_3 polymer, with water of crystallisation on the surface or occupying voids in the crystal lattice, rather than coordinated to the metal ion. This also explains the range of values of x in $\text{MF}_3\cdot x\text{H}_2\text{O}$ reported in the limited literature available.^{1,3} Attempts to react the $\text{MF}_3\cdot x\text{H}_2\text{O}$ with terpy or $\text{Me}_3\text{-tacz}$ under hydrothermal conditions (180 °C, 15 h) were unsuccessful, with the $\text{MF}_3\cdot x\text{H}_2\text{O}$ being recovered, although with noticeably increased crystallinity (sharper PXRD patterns).

These results explain why ‘hydrated’ Group 3 fluorides are not a viable entry into the coordination chemistry of these fluorides with neutral ligands. This contrasts sharply with the Group 13 fluoride hydrates,^{19,29,30} and the Group 4 compounds, [$\text{MF}_4(\text{OH}_2)_2$] (M = Zr, Hf),³¹ whose crystal structures show the water is coordinated to the metal, from which it can be displaced by neutral ligands. These are effective synthons for wider coordination chemistry. We reported previously that

Fig. 1 PXRD patterns obtained from the attempted synthesis of yttrium fluoride hydrate. (A) PXRD of anhydrous YF_3 , A. K. Cheetham and N. Norman, *Acta Chem. Scand., Ser. A*, 1974, **28**, 55; (B) $\text{YF}_3 \cdot x\text{H}_2\text{O}$ (this work); (C) $\text{YF}_3 \cdot x\text{H}_2\text{O}$ after heating under hydrothermal conditions.

the f-block tetrafluorides, $[\text{MF}_4 \cdot x\text{H}_2\text{O}]$ ($\text{M} = \text{Ce}, \text{Th}$) have very limited coordination chemistry ($\text{CeF}_4 \cdot x\text{H}_2\text{O}$ dissolves only very slowly in refluxing dmsol to form $[\text{CeF}_4(\text{dmsol})_2]$). They too are likely to contain only lattice/surface water.³² The wider implications of these results in metal fluoride coordination chemistry suggest that for other metals, only those ‘hydrated’ fluorides that contain water within the metal coordination sphere, are likely to be viable synthons for neutral ligand complexes.

Chloride/iodide precursor complexes

Many trichloride complexes of $\text{Sc}(\text{III})$, $\text{Y}(\text{III})$ and $\text{La}(\text{III})$ with neutral ligands are highly moisture sensitive and must be synthesised and handled in anhydrous systems. In work with other early d-block systems, we noted that the corresponding metal iodides and iodo-complexes were often more soluble in weakly coordinating solvents, probably due to lower lattice energy, although the gain in solubility comes at the cost of even greater moisture sensitivity.^{17,33,34} In the present study we synthesised complexes with $\text{Me}_3\text{-tacn}$ and terpy , which give examples of pseudo-octahedral complexes with *fac* and *mer* geometries for scandium, respectively, although for Y and La higher coordination numbers were often produced. The known²⁶ $[\text{MCl}_3(\text{Me}_3\text{-tacn})]$ ($\text{M} = \text{Y}, \text{Sc}$) were made from $[\text{ScCl}_3(\text{thf})_3]$ or $[\text{YCl}_2(\text{thf})_5][\text{YCl}_4(\text{thf})_2]$ and the triaza macrocycle in anhydrous acetonitrile. The corresponding $[\text{ScCl}_3(\text{BnMe}_2\text{-tacn})]$ was prepared similarly, whilst reaction of

Table 1 ^{45}Sc and $^{19}\text{F}\{^1\text{H}\}$ NMR data^a

Complex	$\delta(^{45}\text{Sc})/\text{ppm}$	$\delta(^{19}\text{F}\{^1\text{H}\})/\text{ppm}$
$[\text{ScCl}_3(\text{Me}_3\text{-tacn})]$	+300	—
$[\text{ScCl}_3(\text{BnMe}_2\text{-tacn})]$	+302	—
$[\text{ScF}_2\text{Cl}(\text{Me}_3\text{-tacn})]$	+219	77.2
$[\text{ScF}_2\text{Cl}(\text{Me}_3\text{-tacn})]$	+155	40.1
$[\text{ScF}_3(\text{Me}_3\text{-tacn})]$	104 (q, $^1J_{\text{Sc-F}} = 219 \text{ Hz}$)	7.7

$[\text{ScCl}_3(\text{terpy})]^b$	+254	—

^a $\text{CH}_3\text{CN}/\text{CD}_3\text{CN}$ except. ^b $\text{CH}_2\text{Cl}_2/\text{CD}_2\text{Cl}_2$.

$\text{LaCl}_3 \cdot 7\text{H}_2\text{O}$ with $\text{Me}_3\text{-tacn}$ in EtOH yielded $[\text{LaCl}_3(\text{Me}_3\text{-tacn})(\text{OH}_2)]$ as a white powdered solid. All complexes have been characterised spectroscopically (IR, ^1H , ^{45}Sc NMR, Table 1, as appropriate) and by microanalysis.

Treatment of YI_3 with one molar equivalent of $\text{Me}_3\text{-tacn}$ in anhydrous acetonitrile under a dinitrogen atmosphere formed a light yellow, extremely moisture sensitive solid, identified as $[\text{YI}_3(\text{Me}_3\text{-tacn})] \cdot 1.5\text{CH}_3\text{CN}$. The ^1H NMR spectrum of the product displayed multiplets at 2.81 and 2.73 ppm, corresponding to the ligand CH_2 groups, as well as a singlet at 2.58 ppm, due to the ligand methyl groups, consistent with *facial* complexation of the $\text{Me}_3\text{-tacn}$. Crystallisation from CH_3CN solution yielded two different crystal morphologies, both of which were analysed by single crystal X-ray diffraction and shown to be $[\text{YI}_3(\text{Me}_3\text{-tacn})] \cdot \text{CH}_3\text{CN}$ (Fig. 2), with the expected tridentate $\text{Me}_3\text{-tacn}$ and three mutually *facial* iodides completing the distorted octahedral environment, and the partial hydrolysis product, $[\{\text{YI}_2(\text{Me}_3\text{-tacn})_2(\mu\text{-O})\}]$ (Fig. 3), formed *via* reaction with trace water. The Y–N bond distances in $[\text{YI}_3(\text{Me}_3\text{-tacn})]$ are similar to those reported in functionalised tacn complexes, e.g. $[\text{Pr}_2\text{-tacn}(\text{CH}_2)_2\text{N}^t\text{Bu}]\text{Y}(\text{CH}_2\text{SiMe}_3)_2$.³⁵

Ellipsoids are drawn at the 50% probability level and H atoms are omitted for clarity. Selected bond lengths (Å) and angles ($^\circ$): Y1–I1 = 3.0213(6), Y1–I2 = 2.9969(7), Y1–O1 = 2.0332(5), Y1–N2 = 2.580(5), Y1–N1 = 2.473(5), Y1–N3 = 2.495(5), Y1–O1–Y1 = 180.00(3), I2–Y1–I1 = 93.991(19), O1–Y1–I1 = 104.69(2), O1–Y1–I2 = 104.12(2), O1–Y1–N2 = 156.16(11), O1–Y1–N1 = 90.72(11), O1–Y1–N3 = 93.79(11).

Fig. 4 Structure of *mer*- $[\text{ScCl}_3(\text{terpy})]$ with ellipsoids drawn at 50% probability level. H atoms are omitted for clarity. Selected bond lengths (Å) and angles ($^\circ$): Sc1–Cl1 = 2.414(2), Sc1–Cl2 = 2.396(2), Sc1–Cl3 = 2.451(2), Sc1–N1 = 2.229(4), Sc1–N2 = 2.231(5), Sc1–N3 = 2.248(4), Cl1–Sc1–Cl3 = 174.51(7), Cl2–Sc1–N2 = 174.2(1), N1–Sc1–N3 = 142.3(2), N1–Sc1–N2 = 71.3(2), N2–Sc1–N3 = 71.1(2), N2–Sc1–Cl3 83.7(1), Cl3–Sc1–Cl2 91.22(6), Cl2–Sc1–N1 = 105.9(1).

The reaction of $[\text{ScCl}_3(\text{thf})_3]$ with terpy in anhydrous CH_3CN gave *mer*- $[\text{ScCl}_3(\text{terpy})]$ (Fig. 4).

The complex has a distorted octahedral coordination around the metal centre conferred by the rigid terpy ligand, the angles involving the ligand are significantly less than the $180/90^\circ$ expected for a regular octahedron, with $\text{N1–Sc1–N3} = 142.3^\circ$. The extended crystal structure of $[\text{ScCl}_3(\text{terpy})]$ shows π -stacking interactions (3.82 \AA) between the aromatic ring of the terpy ligand of the adjacent molecule, connecting them into 1D zig-zag chains (see ESI Fig. S4†).

Reaction of $[\text{YCl}_2(\text{thf})_5][\text{YCl}_4(\text{thf})_2]$ with terpy in CH_3CN yields the colourless complex $[\text{YCl}_3(\text{terpy})(\text{OH}_2)]$ incorporating adventitious water and characterised spectroscopically and by

Fig. 5 Crystal structure of $[\text{YCl}_3(\text{terpy})(\text{OH}_2)]$ with ellipsoid drawn at 50% probability level. H atoms are omitted for clarity. Selected bond lengths (Å) and angles ($^\circ$): Y1–Cl1 = 2.572(2), Y1–Cl2 = 2.611(2), Y1–Cl3 = 2.629(1), Y1–N1 = 2.507(5), Y1–N2 = 2.480(4), Y1–N3 = 2.514(5), Y1–O1 2.348(3), Cl2–Y1–Cl1 176.49(5), Cl3–Y1–Cl1 90.77(5), Cl1–Y1–O1 96.6(1), Cl1–Y1–N2 96.3(1), Cl2–Y1–N2 80.8(1), N2–Y1–N1 64.9(2).

microanalysis. Confirmation of the seven-coordinate geometry follows from a crystal structure determination (Fig. 5).

The crystal structure (Fig. 5) shows a pentagonal-bipyramidal coordination around the metal centre with the Y–Cl bond lengths in the axial positions shorter than that in the equatorial plane. The angle between the yttrium centre and the nitrogen atoms are less than the 72° value expected for the perfect pentagonal-bipyramidal conformation, due to the rigid terpy ligand and the equatorial plane is puckered. Furthermore, the packing in the crystal structure shows both H-bonding ($\text{Cl}\cdots\text{HOH}$) between adjacent molecules to form associated dimers, and weak π -stacking (4.04 \AA) linking the dimers into zig-zag chains (Fig. S5†). The bond lengths are generally shorter than in the eight-coordinate $[\text{YCl}(\text{terpy})(\text{OH}_2)_4]\text{Cl}_2\cdot 2\text{H}_2\text{O}$.³⁶

Using the heavier f-block ions, La(III) and Lu(III), $[\text{LaCl}_3(\text{terpy})(\text{OH}_2)]\cdot 4\text{H}_2\text{O}$ and $[\text{LuCl}_3(\text{terpy})(\text{OH}_2)]$ were obtained *via* reaction of $\text{LaCl}_3\cdot 7\text{H}_2\text{O}$ or $\text{LuCl}_3\cdot 6\text{H}_2\text{O}$, respectively, with one mol. equiv. of terpy in ethanol. X-ray crystallographic analyses show that the La(III) complex exists as a chloro-bridged dimer, $[\{\text{La}(\text{terpy})(\text{OH}_2)\text{Cl}_2\}_2(\mu\text{-Cl})_2]$ (Fig. 6) involving eight-coordinate La(III) with adjacent molecules linked into chains *via* H-bonding interactions between the coordinated water molecule on one La(III) centre and the Cl ligands on adjacent molecules (Fig. S6†). On the other hand, $[\text{LuCl}_3(\text{terpy})(\text{OH}_2)]$ (Fig. S7†) is a seven-coordinate monomer, isostructural with the Y(III) analogue above (and hence also displaying the same H-bonding and π -stacking interactions in the solid state).

Chloride(iodide)/fluoride exchange reactions using $[\text{NMe}_4]\text{F}$

Addition of three mol. equiv. of anhydrous $[\text{NMe}_4]\text{F}$ to a CH_3CN solution of $[\text{ScCl}_3(\text{Me}_3\text{-tacn})]$ gave a colourless solution whose $^{19}\text{F}\{^1\text{H}\}$ and ^{45}Sc NMR spectra³⁷ each showed three

Fig. 6 Crystal structure of $[\text{La}(\text{terpy})(\text{OH})_2\text{Cl}_2]_2(\mu\text{-Cl})_2$ with ellipsoids drawn at 50% probability level. H atoms are omitted for clarity. Selected bond lengths (Å) and angles ($^\circ$): La1–Cl1 = 2.8385(9), La1–Cl2 = 2.8014(8), La1–Cl3 = 2.8895(9), La1–N1 = 2.638(3), La1–N2 = 2.678(3), La1–N3 = 2.658(3), La1–O1 = 2.576(3), La1–Cl3ⁱ = 2.9209(9), Cl1–La1–Cl3 = 144.65(2), Cl1–La1–Cl2 = 86.82(2), Cl1–La1–O1 = 72.14(7), Cl2–La1–O1 = 78.77(7), Cl3–La1–O1 = 140.69(7), N3–La1–N1 123.52(9), N3–La1–O1 145.03(9), N3–La1–N2 = 62.21(9).

broadened resonances at 77.2, 40.1 and 7.7 ppm ($^{19}\text{F}\{^1\text{H}\}$) and 219, 155 and 104 ppm (^{45}Sc) (Fig. 7, Table 1), corresponding to $[\text{ScFCl}_2(\text{Me}_3\text{tacn})]$ (very minor), $[\text{ScF}_2\text{Cl}(\text{Me}_3\text{tacn})]$ and

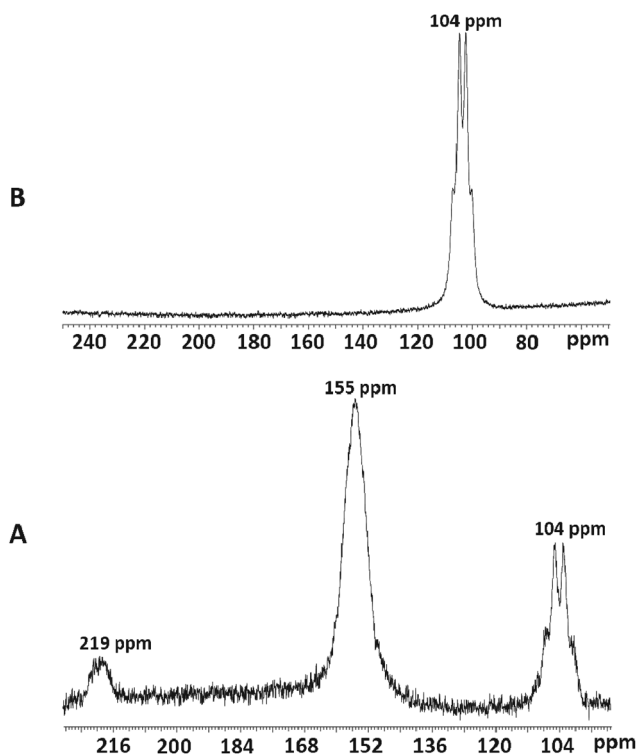

Fig. 7 Fluorination of $[\text{ScCl}_3(\text{Me}_3\text{tacn})]$: A: ^{45}Sc NMR showing the species $[\text{ScFCl}_2(\text{Me}_3\text{tacn})]$ (219 ppm), $[\text{ScF}_2\text{Cl}(\text{Me}_3\text{tacn})]$ (155 ppm) and $[\text{ScF}_3(\text{Me}_3\text{tacn})]$ (104 ppm) when a deficit of $[\text{NMe}_4]\text{F}$ is used; B: ^{45}Sc NMR of $[\text{ScF}_3(\text{Me}_3\text{tacn})]$ showing the quartet at 104 ppm ($J_{\text{Sc-F}} = 219$ Hz).

$[\text{ScF}_3(\text{Me}_3\text{tacn})]$, respectively. The modest quadrupole moment of ^{45}Sc ($I = 7/2$) means that resonances are observed in many systems, but couplings to other nuclei are often lost in the line broadening, unless the scandium is in a high symmetry environment.^{17,34,38,39} Since these complexes are the first examples of scandium fluoride species with neutral ligands, there are no comparable literature data, but the chemical shifts of the chloro-species are reasonable compared to data on other ScCl_3 adducts.^{34,38,39}

Adding further small aliquots of $[\text{NMe}_4]\text{F}$ in CH_3CN initially led to depletion of the resonances assigned to the mixed chloro/fluoro complexes, and enhancement of the broadened quartet at $\delta = 104$ ppm, attributed to $[\text{ScF}_3(\text{Me}_3\text{tacn})]$ (Fig. 7). The broad quartet shows coupling to three equivalent fluorides with $J_{\text{ScF}} = 219$ Hz (since the efg is small). However, excess fluoride caused complete loss of all the ^{45}Sc and $^{19}\text{F}\{^1\text{H}\}$ resonances from the tacn complexes (see below).

The $^{19}\text{F}\{^1\text{H}\}$ and ^{45}Sc NMR data for the fluorination reaction are also strongly indicative of the fluorination of $[\text{ScCl}_3(\text{Me}_3\text{tacn})]$ occurring in a stepwise manner. Further confirmation of this follows from a single crystal X-ray structure determination on $[\text{ScF}_2\text{Cl}(\text{Me}_3\text{tacn})]$, a few crystals of which were grown by concentrating the NMR solution in acetonitrile (Fig. 8).

The complex is six-coordinate with the three nitrogen atoms of the ligand coordinated to the metal in a *facial* conformation, while the three other positions are occupied by two fluorine atoms and one chlorine, with no evidence for disorder being present. As expected, the Sc–F bonds are significantly shorter than the Sc–Cl bond (1.94 against 2.44 Å). The analogous $[\text{ScCl}_3(\text{BnMe}_2\text{-tacn})]$ shows similar behaviour with $[\text{NMe}_4]\text{F}$, with $[\text{ScF}_3(\text{BnMe}_2\text{-tacn})]$ showing a broad ^{45}Sc NMR resonance at 104 ppm, with $\delta(^{19}\text{F}\{^1\text{H}\}) = 10.1$ ppm.

Fig. 8 Crystal structure of $[\text{ScF}_2\text{Cl}(\text{Me}_3\text{tacn})]$ with ellipsoids drawn at the 50% probability level. H atoms are omitted for clarity. Select bond lengths (Å) and angles ($^\circ$): Sc1–F1 = 1.947(3), Sc1–F2 = 1.940(3), Sc1–Cl1 = 2.444(2), Sc1–N1 = 2.339(5), Sc1–N2 = 2.364(4), Sc–N3 = 2.334(4), Cl1–Sc1–F1 = 101.7(1), Cl1–Sc1–N1 = 162.4(1), Cl1–Sc1–N2 = 89.9(1), F1–Sc1–F2 = 103.3(1), N2–Sc1–N3 = 74.6(1), F1–Sc1–N3 = 158.8(1).

Attempts to react $[\text{ScCl}_3(\text{terpy})]$ with dry $[\text{NMe}_4]\text{F}$ in CH_3CN on an NMR scale caused complete loss of the resonances from the trichloro complex, without the appearance of any new resonances in either the ^{45}Sc or ^{19}F spectra.

The reaction of $[\text{YCl}_3(\text{Me}_3\text{-tacn})]$ with three equivalents of $[\text{NMe}_4]\text{F}$ in CH_3CN resulted in a white precipitate that was insoluble in CH_3CN or CH_2Cl_2 and the ^1H NMR spectrum of the solution showed liberation of $\text{Me}_3\text{-tacn}$, whilst the ^{19}F NMR spectrum showed only small amounts of free fluoride. Similar results were obtained using $[\text{YI}_3(\text{Me}_3\text{-tacn})]$, and it was concluded that $\text{Cl}(\text{I})/\text{F}$ exchange resulted in decomposition and loss of the $\text{Me}_3\text{-tacn}$ from the yttrium. Similar decomposition occurred using $[\text{LaCl}_3(\text{Me}_3\text{-tacn})(\text{OH}_2)]$.

Chloride/fluoride exchange reactions using Me_3SnF

Me_3SnF is a useful fluorinating agent, its polymeric structure makes it insoluble in most solvents,^{40,41} but it dissolves as the Cl/F exchange reaction proceeds, and usually, the Me_3SnCl (which contains *tbp* tin centres weakly chlorine-bridged into polymeric chains)⁴² formed is easily removed from the products by washing with hexane. The reagent does not provide free fluoride ions so an excess can be used without the risk of the decomposition observed using $[\text{NMe}_4]\text{F}$. The *fac*-octahedral trifluoro complexes $[\text{ScF}_3(\text{R}_3\text{-tacn})]$ were readily obtained by treatment of the trichloro species with three mol. equiv. of Me_3SnF (and adding excess Me_3SnF has no further effect) (Fig. 9). The broad “doublets” observed in the $^{19}\text{F}\{^1\text{H}\}$ NMR spectra result from partial collapse of the couplings to ^{45}Sc ($I = 7/2$) in the low symmetry environments.

However, the product obtained had a microanalysis corresponding to $[\text{Sc}(\text{Me}_3\text{-tacn})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}]$; note that whilst three equivalents of Me_3SnCl are produced in the reaction, only one is retained in the scandium complex.

Crystals of $[\text{Sc}(\text{Me}_3\text{-tacn})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}]$ were obtained by slow evaporation from a solution of the product in CH_3CN . The X-ray crystal structure confirms the presence of three mutually *facial* fluoride ligands, with the tridentate triaza macrocycle completing the distorted octahedral geometry at Sc with $\text{Sc}-\text{F} = 1.980(6)$, $1.92(2)$ and $\text{Sc}-\text{N} = 2.334(6)$, $2.351(4)$ Å. The $[\text{ScF}_3(\text{Me}_3\text{-tacn})]$ complex acts as a neutral Lewis base towards the Me_3SnCl Lewis acid through one bridging fluoride ligand, $\text{Sc}-\text{F}1 = 1.980(6)$, Å, $\text{Sn}1-\text{F}1 = 2.307(6)$ Å (Fig. 10). This results in a trigonal bipyramidal geometry at Sn, with the Cl and F ligands in the axial positions and a near linear $\text{F}-\text{Sn}-\text{Cl}$ unit ($178.7(2)^\circ$). The $\text{Sc}-\text{N}$ and $\text{Sc}-\text{F}_{\text{terminal}}$ bonds are similar to those in $[\text{ScF}_2\text{Cl}(\text{Me}_3\text{tacn})]$, but the $\text{Sc}-\text{F}(\text{Sn})$ bond is significantly longer. The $\text{Sn}-\text{F}$ bond is longer than that in Me_3SnF ($2.1620(7)$ Å),⁴¹ whilst the $\text{Sn}-\text{Cl}$ is also longer than that in Me_3SnCl polymer ($2.430(2)$ Å).⁴² The Lewis basic properties of *fac*- $[\text{MF}_3(\text{R}_3\text{-tacn})]$ ($\text{M} = \text{Al}, \text{Ga}, \text{Fe}, \text{Cr}, \text{etc.}$) complexes has been noted previously, and exploited to form mixed metal species with alkali metal⁴³ and lanthanide cations, the latter with applications as molecular magnets.⁴⁴

The only similar complex to have been reported is $[\text{ScL}(\mu\text{-F})_2(\text{SnMe}_3\text{Br})_2]$ ($\text{L}^- = \text{N}, \text{N}'\text{-}(1,3\text{-dimethyl-1,3-propanediylidene})\text{bis}(\text{N}', \text{N}'\text{-diethyl-1,2-ethanediamine})$), made from $[\text{ScLBr}_2]$ and Me_3SnF .¹³

Fig. 9 $^{19}\text{F}\{^1\text{H}\}$ NMR spectra of $[\text{ScF}_2\text{Cl}(\text{Me}_3\text{tacn})]$ (77.2 ppm), $[\text{ScF}_2\text{Cl}(\text{Me}_3\text{tacn})]$ (40.1 ppm) and $[\text{ScF}_3(\text{Me}_3\text{tacn})]$ (7.7 ppm). A: ~ 2.5 mol. equiv. of Me_3SnF were added to a CD_3CN solution of $[\text{ScCl}_3(\text{Me}_3\text{tacn})]$; B: < 3 mol. equiv. of Me_3SnF were added to a CD_3CN solution of $[\text{ScCl}_3(\text{Me}_3\text{tacn})]$; C: > 3 mol. equiv. of Me_3SnF were added to a CD_3CN solution of $[\text{ScCl}_3(\text{Me}_3\text{tacn})]$.

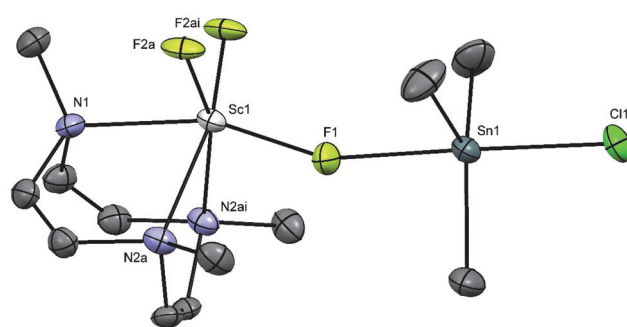

Fig. 10 Crystal structure of $[\text{Sc}(\text{Me}_3\text{-tacn})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}]$ with atom numbering scheme. Ellipsoids are shown at the 50% probability level and H atoms are omitted for clarity. Selected bond lengths (Å) and angles ($^\circ$): $\text{Sc}1-\text{N}1 = 2.334(6)$, $\text{Sc}1-\text{N}2 = 2.351(4)$, $\text{Sc}1-\text{F}1 = 1.980(6)$, $\text{Sc}1-\text{F}2\text{a} = 1.92(2)$, $\text{Sn}1-\text{F}1 = 2.307(6)$, $\text{Sn}1-\text{Cl}1 = 2.502(2)$, $\text{Sn}1-\text{C}1 = 2.124(7)$, $\text{Sn}1 = \text{C}2^{\text{a}} = 2.153(3)$, $\text{N}2-\text{Sc}1-\text{N}2 = 75.36(18)$, $\text{N}1-\text{Sc}1-\text{N}2 = 74.92(14)$, $\text{F}2^{\text{a}}-\text{Sc}1-\text{N}1 = 94.6(10)$, $\text{F}1-\text{Sc}1-\text{N}1 = 159.7(3)$, $\text{F}1-\text{Sn}1-\text{Cl}1 = 178.7(2)$.

The ^{45}Sc and $^{19}\text{F}\{^1\text{H}\}$ NMR spectra of $[\text{Sc}(\text{Me}_3\text{-tacn})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}]$ and $[\text{ScF}_3(\text{Me}_3\text{-tacn})]$ in CH_3CN are identical, as are the ^1H resonances of the $\text{Me}_3\text{-tacn}$ moieties, whilst the ^1H

NMR resonance of the Me_3SnCl in the former complex is consistent with the free organotin, indicating the adduct is dissociated in solution. Me_3SnCl is a weak Lewis acid and complexes such as $[\text{Me}_3\text{SnCl}(\text{Ph}_3\text{PO})]$ also appear largely dissociated in solution.⁴⁵ However, attempts to crystallise $[\text{ScF}_3(\text{Me}_3\text{-tacn})]$ from solutions of $[\text{Sc}(\text{Me}_3\text{-tacn})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}]$ failed with the bimetallic species reformed in the isolated solid. This contrasts with $[\text{ScL}(\mu\text{-F})_2(\text{Me}_3\text{SnBr})_2]$ which decomposes when the mother liquor is removed.¹³ Gently heating a finely ground sample of $[\text{Sc}(\text{Me}_3\text{-tacn})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}]$ (40 °C) under vacuum leads to partial removal of the Me_3SnCl , but complete removal of the tin species could not be achieved without decomposition of the scandium moiety.

The reaction of $[\text{ScCl}_3(\text{terpy})]$ with three equivalents of Me_3SnF gave a white solid identified by microanalysis and multinuclear NMR as $[\text{Sc}(\text{terpy})\text{F}(\mu\text{-F})_2(\text{SnMe}_3\text{Cl})_2]$. The $^{19}\text{F}\{^1\text{H}\}$ NMR (CD_3CN) $\delta = -37.7$ (br s, [2F]), -53.3 (br s, [F]) and ^{45}Sc NMR $\delta = 64$ (s, br) are consistent with the formulation. However, in contrast to $[\text{Sc}(\text{Me}_3\text{-tacn})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}]$, $[\text{Sc}(\text{terpy})\text{F}(\mu\text{-F})_2(\text{SnMe}_3\text{Cl})_2]$ is unstable in solution and slowly deposits a white insoluble solid.

The reaction of $[\text{YCl}_3(\text{Me}_3\text{-tacn})]$ with Me_3SnF in CH_3CN resulted in decomposition, and no YF_3 complex was identified.

Unlike the trichloro analogues, which are very hydrolytically sensitive, solutions of $[\text{ScF}_3(\text{Me}_3\text{-tacn})]$ and $[\text{ScF}_3(\text{BnMe}_2\text{-tacn})]$ in water at neutral pH are stable for many weeks, monitored by ^{19}F and ^{45}Sc NMR spectroscopy, and to heating aqueous solutions at 80 °C for several hours. The complexes are decomposed by excess F^- , and by Na_3PO_4 and Na_2CO_3 (which have a pH ~ 9), but are stable to a 10-fold excess of Cl^- or MeCO_2^- .

Conclusions

The $[\text{ScF}_3(\text{Me}_3\text{-tacn})]$ and $[\text{ScF}_3(\text{BnMe}_2\text{-tacn})]$, which represent the first reported examples of scandium fluoride complexes with neutral co-ligands, have been prepared by Cl/F exchange reactions from the corresponding chlorides, using $[\text{NMe}_4]\text{F}$. Attempts to isolate similar complexes of Y or La, or $[\text{ScF}_3(\text{terpy})]$ have been unsuccessful. In these cases fluorination is accompanied by dissociation of the neutral ligands and formation of insoluble MF_3 . Highly unusual $[\text{Sc}(\text{terpy})\text{F}(\mu\text{-F})_2(\text{SnMe}_3\text{Cl})_2]$ and $[\text{Sc}(\text{Me}_3\text{-tacn})\text{F}_2(\mu\text{-F})\text{SnMe}_3\text{Cl}]$ have been isolated using Me_3SnF as the fluoride source. The high stability of $[\text{ScF}_3(\text{R}_3\text{-tacn})]$ in water over a range of temperatures and pHs, as well as towards common ions such as Cl^- or MeCO_2^- , indicates that are worth further examination to determine their potential as possible carriers for ^{18}F in PET imaging radio-tracers.

The decomposition of analogous Y and La trichloride complexes upon attempted fluorination, indicates that the $\text{R}_3\text{-tacn}$ or terpy ligands are insufficiently strongly bound to these metal ions to prevent their dissociation and formation of MF_3 polymer. Since Y and La are larger than Sc, tetra-azamacrocycles (cyclen or cyclam) may be better suited. Alternatively, anionic pendant arm ligands such as the $\text{H}_2\text{-R-NOTA}$ type,

which will bind more strongly, may be better for these oxophilic metal centres. These possibilities will be investigated in future work.

Conflicts of interest

There are no conflicts to declare.
