Design, synthesis, and biological evaluation of AV6 derivatives as novel dual reactivators of latent HIV-1†

Mingtao Ao,^{‡a} Zhenrui Pan,^{‡a} Yuqing Qian,^{‡a} Bowen Tang,^a Zeming Feng,^{ID a} Hua Fang,^c Zhen Wu,^a Jingwei Chen,^{*b} Yuhua Xue^{*a} and Meijuan Fang^{ID *a}

The “shock and kill” strategy might be a promising therapeutic approach for HIV/AIDS due to the existence of latent viral reservoirs. A major challenge of the “shock and kill” strategy arises from the general lack of clinically effective latency-reversing agents (LRAs). The 2-methylquinoline derivative, antiviral 6 (AV6) has been reported to induce latent HIV-1 expression and act synergistically with a HDAC inhibitor VA to reverse HIV latency. We report herein the design and identification of AV6 analogues which possess the zinc-binding group of HDAC inhibitors and have dual acting mechanism for the reactivation of HIV-1 from latency. Evaluation of compounds for the reactivation of HIV-1 latency identified two excellent active compounds **12c** and **12d**. Further bioassays revealed that these two compounds reactivated latent HIV-1 through dual mechanism, the inhibition of HDACs and NFAT-required for early HIV-1 gene expression. Additionally, it was found that **12c** and **12d** could reactivate HIV-1 transcription by releasing P-TEFb from the inactive complex 7SK snRNP. At last, molecular docking identified their orientation and binding interactions at the active site of HDAC2. This experimental data suggests that **12c** and **12d** can be served as effective HIV-1 LRAs which can be taken up for further studies.

1. Introduction

The latent HIV reservoirs in infected patients are the major barrier to eliminate HIV as reported.^{1,2} Recently, scientists have made efforts to use the “shock and kill” strategy to eradicate latently infected cells.^{3–10} In the “shock and kill” approach, latency-reversing agents (LRAs) should be used to force the replication and expression of latent HIV proviruses in the initial “shock” phase, and then the reactivated cells would be eliminated (“kill” phase) by a combination of viral cytopathic effects and the host immune response, as well as concomitant highly active anti-retroviral therapy (HAART) to prevent new infections.^{11–13} Currently, a wide range of small molecule have been explored as LRAs to reactivate latent provirus, including histone deacetylase (HDAC) inhibitors (Fig. 1), methyltransferase inhibitors, protein kinase C (PKC) activators, positive

transcription elongation factor b (P-TEFb) activators and other unclassified HIV-1 latency-reversing agents.^{14–18} HDAC inhibitors, such as valproic acid (VA), vorinostat (also known as SAHA), and panobinostat have been used in clinical trials in HIV.^{19–23} However, preclinical and clinical studies suggest that these LRAs which target a single mechanism involved in latency may not be efficient enough to reactivate latent HIV-1 *in vivo*.^{24–27} Hence, there is an urgent requirement of developing more effective latency-reversing interventions with a unique structure and effective mode of action.

Antiviral 6 (AV6, Fig. 1), a novel HIV-1 latency-reversing agent identified through high-throughput screening, has been reported to reproducibly activate latent HIV-1 in different cell-based latency model systems without causing general T cell proliferation or activation.²⁸ Its activation is independent of the site of provirus integration, which complements the latency antagonist activity of HDAC inhibitor. For example, AV6 was demonstrated to act cooperatively with VA (a HDAC inhibitor) for enhanced induction of HIV-1 gene expression.²⁸ This is a proof of concept showing that the combination of two or more inducers of HIV gene expression acting in accord *via* different mechanisms may produce a more potent reactivation effect.^{29,30} In this study, we design the AV6 analogues as LRAs with the goal of achieving HDACs inhibition. Key to the design is to identify the attachment appoint and the linker for the introduction of the essential active group of HDACs. Herein, we performed the chemical synthesis and biological evaluation of the first chemical series of AV6 analogues (**series I**) to determine the suitable

attachment point for the introduction of the functional group of HDAC inhibitor. Then, a linker optimization strategy was pursued to obtain effective LRAs bearing AV6 scaffold structure and the functional group of HDAC inhibitors. These new AV6 derivatives (**series II**) were evaluated for their reactivation of latent HIV. The most potent reactivators were then taken up to do further bioassays.

2. Results and discussion

2.1. Design of the target compounds

Multi-targeted drugs have emerged as an innovative therapeutic approach for many diseases due to their complex etiology and their multifactorial progression.^{31–33} AV6 and HDAC inhibitors have been validated as two inducers of HIV gene expression acting in accord *via* two different mechanisms. The *N*-phenylquinoline nucleus of AV6 is considered as ‘Master Key Core’ in many compounds aimed at different targets to bring out varied pharmacological properties. Besides, many HDACis have been designed and synthesized as dual- or multi-targeted inhibitors for the cancer therapy,³⁴ and the synergistic effect on the activation of latent provirus between VA (a carboxylate HDACi) and AV6 has been confirmed.²⁸ Thus, we developed an idea that the introduction of the function groups of HDACis in the *N*-phenylquinoline structural scaffold of AV6 might also result in new compounds both targeting HDACs and with AV6 related active mechanism to generate more potent LRAs.

There are only three class I HDACs (HDAC 1, HDAC 2, HDAC 3) which are localized at the integrated HIV-1 LTR and are zinc-dependent deacetylases.^{14,35} The classical pharmacophore for their HDACi consists of a zinc-binding group (ZBG), an appropriate linker and a surface recognition cap group.³⁶ Generally, ZBG plays a significant role in the binding efficiency between HDACi and enzyme. Therefore, we intend to incorporate the essential active group ZBG of HDACis into the *N*-phenylquinoline scaffold to generate new small molecule entities (AV6 analogues) which may display better potency to activate latent HIV-1. However, this is not a straight-forward procedure, and we must identify the appropriate common features, substitution sites, and then growing vectors.

We hypothesized that the substituents on the benzene or quinoline rings contained in AV6 structure might modulate the activation activity of the compound. Therefore, we initially designed **series I** derivatives (Fig. 2, compounds **7b–7B**) of AV6 to evaluate the influence of different substituents and various attachment points on the activation activity and figure out the best site for the introduction of the functional group ZBG of the HDACis. There are various ZBGs for HDACi, such as hydroxamic acids, aminobenzamides, carboxylates (short-chain fatty acids), electrophilic ketones, thiols, mercaptoacetamides, and 3-hydroxypyridin-2-thiones. Among all types of ZBGs, hydroxamic acid and carboxylates with different linker were subsequently incorporated into the suitable site of *N*-phenylquinoline nucleus in order to identify more potent novel LRAs (Fig. 2, **series II**). In this paper, we report the design, synthesis, and biological evaluation of AV6 analogues as novel LRAs with dual activated mechanism.

2.2. Syntheses of the designed compounds

The synthetic approaches for the two different series of target compounds are outlined in Scheme 1 and 2. Compounds **7a–7w** were prepared according to a four-step procedure described previously and shown in Scheme 1.³⁷ *p*-Anisidine was condensed with ethyl acetoacetate to form compound **2**, which was cyclized in diphenyl ether affording 6-methoxy-4-hydroxy-2-methylquinoline (**3**). The treatment of **3** with phosphorus oxychloride to provide the key intermediate 4-chloro-6-methoxy-2-methylquinoline (**4**).^{38–40} Compounds **7a–7e** could be easily obtained through the reaction of **4** with different nucleophilic amine derivatives in the presence of catalytic amount of HCl. On the other hand, demethylation of **4** using BBr₃ produced 4-chloro-2-methylquinolin-6-ol (**5**). Alkylation of **5** with bromoethane or 2-bromopropane provided **6a** or **6b**, and the reaction of halides (**6a** or **6b**) with corresponding amine derivatives produced compounds **7f–7w** (Scheme 1).^{41,42}

The designed products **9a–9e**, **10a–10d**, **11a–11d** and **12a–12d** (**series II**) were synthesized according to the pathway shown

HCl, 120 °C, 5 h.

in Scheme 2. Demethylation on C-6 position of compound **7a** gave corresponding C6–OH quinolone (**8**). Compound **8** converted to compounds **9a–9e** and **10a–10d** by alkylation of the C6–OH with appropriate alkyl halide and various lengths of ethyl or methyl bromoalkanoate, respectively. Carboxylic acid derivatives **11a–11d** were finally obtained by the hydrolysis of esters **10a–10d**. Conversion of esters **10a–10d** to hydroxamic acids using freshly prepared hydroxylamine yielded the target compounds **12a–12d**.⁴³

The structures of the target compounds were confirmed with ¹H-NMR, ¹³C-NMR, and high-resolution mass spectrometry (HRMS).

2.3. Biological evaluation

2.3.1 Reactivation of latent HIV-1 gene expression in J-Lat A2 cells and structure–activity relationship. All target compounds were first evaluated for their activation of latent HIV-1 in J-Lat A2 cells, which contained an integrated 5′-LTR-Tat-Flag-iRES-EGFP-3′-LTR expression cassette that was normally silent, the enhanced green fluorescent protein (GFP) would be expressed under the control of 5′LTR promoter upon activation.⁴⁴ In this screening experiment, AV6 and SAHA were employed as positive controls. The results are presented in Tables 1–3. The structure–activity relationship (SAR) was further explored as described below.

At the first initial exploration, a variety of substituents and different attachment points at the benzene or quinoline rings contained in AV6 structure were examined. As shown in Table 1,

compound **7a** (AV6) with 6-methoxy and 3′,4′-dichloro substitutions induced 57.0 ± 1.2 percent GFP production in J-Lat A2 cells at 10 μM. Upon comparison of the activities of 6-ethoxy derivatives **7f–7j** and 6-isopropoxy derivatives **7o–7s** with 6-methoxy derivatives **7a–7e**, we found that the reactivation potency of the derivatives for latent HIV-1 is very sensitive to the type of R₁ substituent. Compounds **7o–7s** have no effect on HIV-1 gene expression in J-Lat A2 cells, which suggest that the replacement of the methoxy group with the isopropoxy group at C-6 position of quinoline ring is very detrimental for the reactivation potency of latent HIV-1. While in 6-ethoxy derivatives **7f–7j**, **7f** exhibits good activity of latent HIV-1 reversing (47.3 ± 3.3% at 10 μM), and compounds **7g–7i** produce enhanced potency (14.5–39.9% of the GFP expression at 10 μM) compared to corresponding 6-methoxy derivatives **7b–7d** (with GFP% values ranged from 2.1–8.3% at 10 μM). These results imply that the C-6 position (R₁) of the quinoline ring may be a promising attachment point for the introducing of the ZBG groups by using the linear alkyl linker.

On the other hand, the replacement of Cl with linker groups (CH₃ (**7d** and **7r**) and OCH₃ (**7e**, **7j**, **7s**, and **7z**)), ZBG groups (COOH (**7l** and **7u**), COOR (**7m** and **7v**), and CONHOH (**7n** and **7y**)), or other groups (NO₂ (**7k**, and **7t**)) at the C-3′ (R₃) and C-4′ (R₄) positions of phenyl ring leads to the disappearance of activity as shown in Table 1. It indicates that 3′,4′-dichloro substitutions at the phenyl ring are essential for potent reactivation of latent HIV-1 gene expression. Moreover, compounds **7A** (5.4 ± 0.4%) and **7B** (1.3 ± 0.3%) in which the phenyl ring is

Scheme 2 Synthesis of 3-((4-((3,4-dichlorophenyl)amino)-2-methylquinolin-6-yl)oxy)-alkanoic acid/hydroxyl acid. Reagents and conditions: (a) BBr₃, DCM, r.t., 2 h; (b) appropriate alkyl halide, NaH, DMF, r.t., overnight; (c) ethyl or methyl bromoalkanoate, NaH, DMF, r.t., overnight; (d) EtOH, 40% NaOH aqueous solution, 50 °C, 1 h; (e) NH₂OH, NaOH, CH₃OH, 0 °C to r.t.

changed to the pyridine ring display weak or no induction of GFP expression in J-Lat A2 cells at 10 μM in comparison with AV6/7a ($57.0 \pm 1.2\%$) and 7f ($47.3 \pm 3.3\%$), respectively. It implies that the phenyl ring is also essential for the activity. Additionally, 7b, 7f–7j, 7m, and 7A also showed certain degree of activation effect (with GFP% values $> 2.0\%$) at 5 μM . Among them, 6-ethoxy derivatives 7f–7j could reactivated latent HIV-1 in a dose-dependent manner better than 6-methoxy derivatives 7a–7e. Above all, the position C-6 (R_1) of quinoline ring might be better suited for the introduction of ZBG group than the positions R_3 and R_4 of benzene ring, and the ZBG group would like to be introduced in R_1 position by using linear linker.

To explore the effect of chain length of linear linker on activity, a series of ether analogues of AV6 (9a–9e) with 3–7 carbons of *n*-alkyl chain at the C-6 position of the quinolone ring was generated and their reactivation of latent HIV-1 gene expression was evaluated. As shown in Table 2, all ether analogues of AV6 (9a–9e) with 3–7 carbons of linear alkyl chain retained potent activities in the induction of GFP expression in

J-Lat A2 cells at 10 μM ($19.7 \pm 0.7\%$ – $32.4 \pm 2.9\%$) and 5 μM ($11.1 \pm 1.8\%$ – $29.1 \pm 2.2\%$). It was further confirmed that together with the oxygen connection, the straight alkyl chain could be used as linear linker for the introduction of ZBG groups at 6-position of quinolone ring.

Finally, we investigated the effect of various ZBG groups with linear alkyl linker connected to the C-6 position of the quinoline ring on latent HIV-1 reactivation. Different ZBG groups (COOC_2H_5 , COOH , and CONHOH) were introduced at the terminal of the straight alkyl chain on 6-position of quinolone ring, and another three series of AV6 analogues (10a–10d, 11a–11d, and 12a–12d) were generated and analyzed. Among these new derivatives with various ZBG groups, compounds 10a–10d (carboxylates) and 11a–11d (carboxylic acids) were either weakly active or completely inactive at tested concentrations (Table 3). Compounds with hydroxamic acid side chain showed varying degrees of potency to reverse HIV latency (12b–12d), except for compound 12a. Compounds 12c and 12d exerted a remarkable improvement in the latent HIV-1 reactivation activity, inducing

39.7 ± 4.1% and 49.9 ± 3.5% GFP production in J-Lat A2 cells at 1 μM, respectively. However, they displayed slightly higher toxicity than SAHA and AV6 according to the cell viability (Table 2). In this experiment, we also observed that the length of the alkyl linker with oxygen bonded connection at the C-6 position had an important effect on the activity. For example, for compounds that had the same terminal basic group –CONHOH, the latency-reversing activity of **12c** (*n* = 5) and **12d** (*n* = 6) were much better than that of **12a** (*n* = 3) and **12b** (*n* = 4). These results indicate that the length of the linear alkyl linker (*n*) and

its terminal basic group (R₅) have important impacts on the compounds regarding their binding activities.

Among all these AV6 analogues, **12c** and **12d** showed the most optimal properties in terms of its efficient latency-reversing activity and displayed relatively mild cytotoxicity, thus they were selected for further bioassays as outlined below.

2.3.2 Compounds 12c and 12d promote HIV-1 LTR-driven GFP expression in different latency cell models. When J-Lat A2 cells were treated with different amounts of AV6, SAHA, **12c**, and **12d**, the percentage of GFP-positive cells induced by

^a Data are presented as mean ± SD of at least three independent experiments performed in triplicate. Cells were treated with the indicated compounds at 1, 5, 10 μM for 24 h. The expression of GFP were evaluated by FACS.

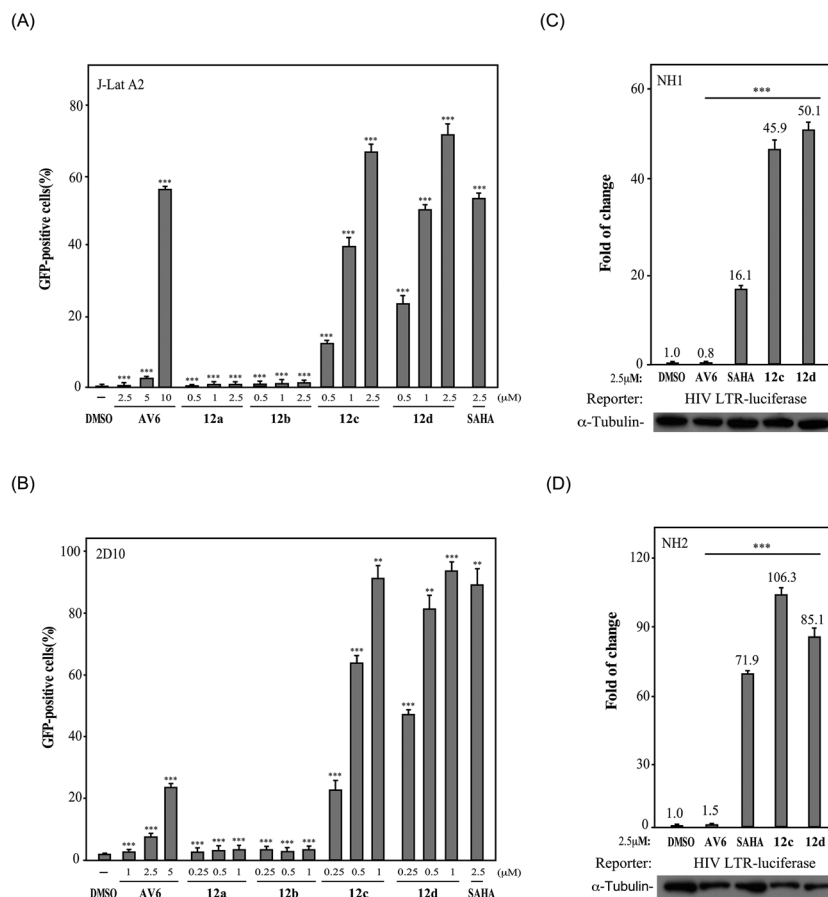

Fig. 3 HIV latency can be reversed by **12c**–**12d** in different latency cell models. (A) J-Lat A2 cells, (B) 2D10 cells, (C) the HeLa-based NH1 cells. (D) The NH2 cells expressing Tat. All tested cells were treated with 0.1% DMSO or the indicated concentrations of the drugs (**12c**, **12d**, SAHA and AV6) for 24 h. The expression of GFP for tested J-Lat A2 and 2D10 cells was measured by FACS. Whole cell extracts for tested NH1 and NH2 cells were prepared and examined for the luciferase activities. The error bars in all panels represent mean \pm SD based on at least three independent experiments. The P value was defined as $**p < 0.01$, and $***p < 0.001$ vs. control.

12c and **12d** increased in a dose-dependent manner (Fig. 3(A)). The stimulatory effect to reactivate latent HIV-1 was also confirmed in 2D10 cell line (Fig. 3(B)), which is another Jurkat-based post-integrative latency model that harbors almost the complete HIV genome except for encoding a partially attenuated Tat variant H13L and the *nef* gene that is replaced by the GFP-coding sequence.⁴⁵ In order to know whether compounds **12c** and **12d** activated latent HIV-1 depend on viral 5'-LTR, we additionally tested the effect of AV6, SAHA, **12c**, and **12d** at 2.5 μ M in NH1 and NH2 cells, which is a pair of HeLa-based isogenic cells line and both of which contain an integrated HIV-1 5'-LTR-luciferase reporter gene but only the latter stably expresses HIV-1 Tat.^{46,47} As shown in Fig. 3(C) and (D), AV6 did not show any activation effect, while compounds **12c** and **12d** induced a significant increase in luciferase activity in both NH1 and NH2, which is much better than SAHA at the same concentration (2.5 μ M). Taken together, these results suggest that compounds **12c** and **12d** promote HIV-1 LTR-driven GFP expression in different latency cell models and give us a hint that previous design of AV6 analogues is reasonable.

2.3.3 Dual mechanism of 12c for the reactivation of latent HIV-1. Compounds **12c** and **12d** were derived from AV6 and

designed by incorporating histone deacetylase (HDAC) inhibitory functionality into the pharmacophore of AV6, as dual-acting HIV LRAs. Previous studies have reported that AV6 acts in part at a posttranscriptional level and synergizes with the HDAC inhibitor valproic acid to reverse HIV latency.²⁸ So we first verified that the synergism can also be found between AV6 and SAHA in J-Lat A2 cells. As shown in Fig. 4(A), the combination of 5 μ M AV6 and 1 μ M SAHA produced 49.0 ± 3.2 of % GFP expression, which is greater than the simple sum (23.9 ± 1.4) of the effects produced by 5 μ M AV6 (3.8 ± 1.1) and 1 μ M SAHA (20.1 ± 0.3). The efficacy is believed to be a result of the synergy between AV6 and SAHA. However, there is no synergy between **12c** and AV6/SAHA (Fig. 4(A)). For example, the combination of 1 μ M SAHA and 1 μ M **12c**, which produced 58.4 ± 3.8 of % GFP expression, almost have the same effect on the activation of latency HIV-1 with the simple sum (59.8 ± 4.4) of 1 μ M SAHA (20.1 ± 0.3) and 1 μ M **12c** (39.7 ± 4.1). Similarly, the combination of 5 μ M AV6 and 1 μ M **12c** produced 44.5 ± 2.9 of % GFP expression which is almost the same as the simple sum (43.5 ± 5.2) of 5 μ M AV6 (3.8 ± 1.1) and 1 μ M **12c** (39.7 ± 4.1). From these findings, we can assume that **12c** may have similar

Fig. 4 **12c** retains the reactivation mechanism of AV6. (A) J-Lat A2 cells were treated with AV6, SAHA, **12c** alone, or in combination for 24 h, and then analyzed by flow cytometry to determine the percentages of GFP(+) cells. (B) J-Lat A2 cells were treated with SAHA, AV6 or **12c** for 24 h, in the presence or absence of the calcineurin inhibitor FK506 (20 μM). The percentages of GFP(+) cells were evaluated by FACS and plotted. Results shown are the means ± SD from three independent experiments. The *P* value was defined as ***p* < 0.01, and ****p* < 0.001 vs. control.

mechanisms with AV6 and SAHA to induce HIV-1 latency reversal.

2.3.3.1 Activate latent HIV-1 via the NFAT-required mechanism. It was reported that AV6 requires nuclear factor of activated T-cells (NFAT) for inducing latent HIV-1 expression, but not SAHA. The function of NFAT is regulated by calcineurin (CaN), a calcium and calmodulin dependent serine/threonine protein phosphatase, which activates the T cells of the immune system and can be blocked by its inhibitors.⁴⁸ To determine whether NFAT is involved in the reversal of HIV latency by **12c**, J-Lat A2 cells were pre-treated with the calcineurin inhibitor FK506 before the incubation with **12c**. As illustrated in Fig. 4(B), the calcineurin inhibitor FK506 could block AV6-dependent viral expression but did not affect the reactivation of HIV latency induced by SAHA. The reactivation of

HIV latency induced by **12c** was decreased after pre-treated with FK506, so FK506 also did block **12c**-dependent viral gene expression to some extent. These results suggest that **12c** retains the reactivation mechanism of AV6, which requires NFAT for early HIV-1 gene expression. While compound **12c** is not as sensitive to FK506 as AV6 is, it indicates that **12c** may activate latent HIV-1 from latent reservoirs as a HDACs inhibitor.

2.3.3.2 Activate latent HIV-1 as histone deacetylase (HDAC) inhibitors. It is well known that inhibition of HDACs is sufficient to reactivate a fraction of latent HIV in a variety of experimental systems. Histone acetylation consists of the addition of an acetyl group to the ε-amino group of lysine residues. Histone lysine acetylation, on lysine 9 or 14 of histone H3 (H3K9, H3K14) or on lysine 16 of histone H4 (H4K16), is generally associated with active gene transcription.^{15,21} Thus, we

Fig. 5 Western blotting analysis of the acetylation levels of histones H3 and H4 in A549 cells (A), HeLa cells (B) and J-Lat A2 cells (C) after **12c** and **12d** treatment respectively for 24 h.

Fig. 6 The HeLa-based F1C2 cells stably expressing the Flag-tagged CDK9 were treated with **12c**, **12d**, or DMSO for 24 h. Nuclear extracts (NE) and anti-Flag immunoprecipitates (IP) derived from NE were analyzed by western blotting for the indicated proteins.

examined whether compounds **12c** and **12d** with the functional group ZBG of HDACs inhibitors also inhibited intracellular even nuclear HDACs by monitoring the acetylation levels of histones H3 and H4 in HeLa and A549, and J-Lat A2 cell lines. In this assay, SAHA (a clinically approved pan-HDAC inhibitor) was used as positive control, DMSO and AV6 were used as negative controls. It was found that after the treatment of compounds **12c** and **12d**, the acetylation of histone H3 and H4 was significantly up regulated in a dose-dependent manner, whereas AV6 which lacked HDAC inhibition activity was not effect on the acetylation levels of histones H3 and H4 (Fig. 5). It indicated that the right introduction of a ZBG (-CONHOH) in the AV6

scaffold generated two excellent LRAs **12c** and **12d**, which possessed strong activity on HDACs inhibition to induce HIV-1 latency reversal.

2.3.4 Compounds 12c and 12d release P-TEFb from the inactive complex 7SK snRNP. Positive transcription elongation factor b (P-TEFb), which is composed of CDK9 and CycT1, is a critical component of the cellular transcriptional machinery that is required for the elongation of HIV transcription.^{49,50} In latently HIV infected cells, most of the cellular P-TEFb are sequestered in inactive complex 7SK snRNP. Besides P-TEFb, this complex also contains the 7SK snRNA that acts as a molecular scaffold to hold the complex together and the protein HEXIM1 and LARP7, which inhibits the CDK9 kinase activity and binds to the 3' end of 7SK snRNA, respectively.^{16,46,51–55} Releasing active P-TEFb from 7SK snRNP should be an excellent strategy to activate viral replication in these cells.⁴⁹ To determine whether **12c** and **12d** are capable of inducing P-TEFb's dissociation from 7SK snRNP, an anti-Flag immunoprecipitation was performed in the HeLa-based F1C2 cells which stably express the Flag-tagged CDK9 (CDK9-Flag),^{51,56} to examine the association of CDK9 with two signature 7SK snRNP components HEXIM1 and LARP7.⁵⁷ Using DMSO as a negative control, it was found that **12c** and **12d** markedly reduced the amounts of HEXIM1 and LARP7 bound to the immunoprecipitated CDK9-Flag (Fig. 6). It indicated that **12c**

Fig. 7 SAHA (A) and **12c** (B) docked into the active site of HDAC2 (PDB entry 4LXZ). SAHA and **12c** are shown in stick with yellow and brown carbon, respectively. The catalytic zinc in magenta CPK representation. The HDAC2 binding site is presented with a coloured ribbon. Neighbouring amino acids were displayed in lines within a distance of 5 Å approximately to ligand. 2D binding models of SAHA (C) and **12c** (D) with HDAC2. Hydrogen bonds are indicated with solid arrows, colour lines around ligands (SAHA and **12c**) stand for the binding pocket and the residues in colours nearby established the pocket. The green colour denotes the hydrophobic nature of amino acids, the red colour denotes the acid amino acids, the purple denotes the alkalinity of amino acids, the cyan denotes the polar amino acids, and the grey points of ligand atoms denotes the solvent accessibility.

and **12d** were able to reactivate HIV-1 transcription by releasing P-TEFb from the inactive complex 7SK snRNP.

2.4. Molecular docking study of compound **12c** and **12d** to HDAC2

SAHA achieves broad HDAC inhibitor activity through recognition of conserved structural features within this family of enzymes. We performed molecular docking study in the HDAC2 to determine the binding mode for AV6 analogues and study the key interactions between AV6 analogues and HDAC2. The X-ray protein structure of the human HDAC2 co-crystallized with SAHA in the ligand binding pocket (PDB code: 4LXZ) was selected to run the docking calculations. Re-docking was first carried out with the co-crystal ligand (SAHA) into the binding site of HDAC2 and compared with the co-crystal pose (4LXZ) to assess the docking protocol in this study. The RMSD value of re-docked SAHA refereeing with the co-crystal pose is 0.773 Å (see Fig. S1 of the ESI†), which indicated our docking results were reliable as the success rate of docking is usually judged using the RMSD value lesser than 2.0 Å. Then, we performed the docking analysis of **12c** binding to HDAC2. Molecular docking study indicated that the docking score of **12c** ($-5.949 \text{ kcal mol}^{-1}$) beyond 2-fold to SAHA ($-2.759 \text{ kcal mol}^{-1}$). Comparison of the binding poses of SAHA and **12c** in the active site of HDAC2 (Fig. 7) shows that the ZBGs of **12c** and SAHA both form interactions with the zinc ion and TYR308, but only the OH group of **12c**'s ZBG establishes an additional hydrogen bond which interacted with the side chain of residue HID145 (distance: 1.96 Å). In addition, the interaction between the surface of binding site and their cap groups was apparently different. The cap group of SAHA phenyl group has π - π stacking interaction with residue HID33, while for **12c** binding mode the quinolone core formed a key π - π stacking interaction with residue TYR209. These findings might lead to the better docking score for **12c** than SAHA. In this work, molecular model of HDAC2 in complex with **12d** was also constructed. It was found that compound **12d** showed a similar binding mode with **12c** (see Fig. S2 of the ESI†).

3. Conclusion

In summary, series of 2-methylquinolin-4-amine compound were synthesized and their ability to activate latent HIV-1 were evaluated in J-Lat A2 cells. Among all synthesized compounds, compound **12c** and **12d** exhibited excellent potency to reverse HIV latency. Compared with the obviously a lot of synergy between SAHA and AV6, no cooperative effect was observed using the combination of **12c** and AV6 for the reactivation of latent HIV-1 gene expression, and to some extent the **12c**-dependent viral gene expression was blocked by the calcineurin inhibitor FK506 which did block AV6-dependent mRNA expression.²⁸ These data indicate that **12c** retains the reactivation mechanism of AV6, which requires NFAT for early HIV-1 gene expression. On the other hand, the western blotting clearly showed that both in the HepG2 cells and A549 cells treated with **12c** and **12d**, the lysine acetylation of histone H3

and histone H4 increased in a dose-dependent manner. This study implies that **12c** and **12d** also act as HDAC inhibitors to reactivate HIV-1 transcription. Positive transcription elongation factorb (P-TEFb) is a critical component of the cellular transcriptional machinery that is required for the elongation of HIV transcription. In this work, the co-immunoprecipitation assay confirmed that **12c** and **12d** were able to release P-TEFb from the inactive complex 7SK snRNP to activate HIV transcription. Molecular docking yielded binding modes for compounds **12c** and **12d** with the similar metal coordination with Zn^{2+} as well as SAHA, and its larger cap group quinoline core increased the interactions with HDAC2 and turned in the opposite direction from the cap group of SAHA. All these results proved the potential of **12c** and **12d** as novel dual reactivator of latent HIV-1. However, further studies are required to determine their roles in reactivating latent HIV-1.

4. Experimental section

4.1. Chemistry

All reagents were commercial available and used without further purification, unless otherwise indicated. Reactions, which required the use of anhydrous, inert atmosphere techniques, were carried out under an atmosphere of nitrogen. Reactions were magnetically stirred and monitored by thin-layer chromatography (TLC) on Merck silica gel 60F-254 by fluorescence. ¹H-NMR and ¹³C-NMR spectra were obtained using a Bruker (Bruker Biospin, Zug, Switzerland) AV2600 Ultrashield spectrometer at 600 and 150 MHz, respectively. Chemical shifts were reported in parts per million (ppm) relative to tetramethylsilane (TMS) as an internal standard. Multiplicities were abbreviated as follows: single (s), doublet (d), doublet of doublets (dd), doublet-triplet (dt), triplet (t), triplet-triplet (tt), triplet-doublet (td), quartet (q), quartet-doublet (qd), multiplet (m), and broad signal (brs). High-resolution mass spectral (HRMS) data were acquired on a Q Exactive. Melting points were measured on a SGW X-4 micro-melting point spectrometer and were uncorrected. The purities of synthesized compounds were assessed by high performance liquid chromatography (HPLC) with a COSMOSIL C18-MS-II column (250 mm × 4.6 mm i.d., 5 μm). The HPLC analysis was performed on an Agilent Technologies 1100 Series HPLC system. The mobile phase was methanol (A) and water (B) in a linear gradient mode as follows: (A) from 5% to 100% and (B) from 95% to 0% during 0–30 min. The flow rate was 1 mL min⁻¹, and the detection wavelengths were 254 nm and 280 nm.

4.1.1 Ethyl 3-((4-methoxyphenyl)imino)butanoate (2). A mixture of *p*-anisidine (**1**) (406.3 mmol, 50.0 g), ethyl acetoacetate (487.2 mmol, 62.0 mL), anhydrous magnesium sulfate (291.0 mmol, 35.1 g) and acetic acid (2.0 mL) in ethanol (100.0 mL) was refluxed at 90 °C for 4 h. After completion of the reaction, the mixture was filtered and concentrated under reduced pressure to give a brown liquid. The residue was purified by flash chromatography on a silica gel (300–400 mesh) using ethyl acetate/petroleum ether as eluant to afford **2** (86.1 g, 90.1%) as a brown liquid. ¹H NMR (600 MHz, DMSO-*d*₆): δ 10.14 (s, 1H, NH), 7.11–7.14 (m, 2H, Ph-H), 6.91–6.93 (m, 2H, Ph-H),

4.62 (s, 1H, C=CH), 4.04 (q, $J = 7.0$ Hz, 2H, OCH₂CH₃), 3.75 (s, 3H, OCH₃), 1.89 (s, 3H, CH₃), 1.19 (t, $J = 7.1$ Hz, 3H, OCH₂CH₃). ¹³C NMR (150 MHz, DMSO-d₆): δ 169.9 (C=O), 160.3 (NHCH₃-C=CH), 157.4 (C-OCH₃), 132.0 (Ph-C), 126.7 (s, 2C, Ph-C), 114.7 (s, 2C, Ph-C), 84.8 (C=CH), 58.5 (OCH₂CH₃), 55.7 (OCH₃), 20.2 (OCH₂CH₃), 15.0 (CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₃H₁₈NO₃⁺, 236.1128, found, 236.1281.

4.1.2 6-Methoxy-2-methylquinolin-4(1H)-one (3). A solution of ethyl 3-[(4-methoxyphenyl) imino] butanoate (2) (85.1 mmol, 20.0 g) in diphenyl ether was heated to 250 °C for 30 min. At the end of the period, the reaction mixture was cooled to 25 °C and diluted with ethyl acetate. Then crystalline solid separated out from the mixture, washed with ethyl acetate (30.0 mL) and dried in vacuum to give 3 (8.3 g, 51.5%) as a white solid. ¹H NMR (600 MHz, DMSO-d₆): δ 7.80 (d, $J = 9.0$ Hz, 1H, H-8), 7.50 (d, $J = 2.8$ Hz, 1H, H-5), 7.45 (dd, $J = 2.8, 9.1$ Hz, 1H, H-7), 6.49 (s, 1H, H-3), 3.88 (s, 3H, OCH₃), 2.54 (s, 3H, CH₃). ¹³C NMR (150 MHz, DMSO-d₆): δ 174.6 (C=O), 156.2 (C-6), 150.5 (C-2), 135.2 (C-9), 124.7 (C-10), 123.1 (C-7), 120.4 (C-8), 107.4 (C-3), 104.1 (C-5), 55.9 (OCH₃), 19.9 (CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₁H₁₂NO₂⁺, 190.0863, found, 190.0862.

4.1.3 4-Chloro-6-methoxy-2-methylquinoline (4). The mixture of 6-methoxy-2-methylquinolin-4-ol (3) (52.9 mmol, 10.0 g) and POCl₃ (60.0 mL) was heated to 110 °C for 2 h. After completion of the reaction, the excess of POCl₃ was removed under reduced pressure. The residue was quenched into ice-water and stirred at 0 °C for 15 min, then the pH was adjusted to 7 with saturated sodium hydroxide solution. The solid obtained was collected by filtration and dried in vacuum to give 4 as a white solid (8.1 g, 73.9%). ¹H NMR (600 MHz, CDCl₃): δ 7.83 (d, $J = 9.2$ Hz, 1H, H-8), 7.31 (d, $J = 2.6$ Hz, 1H, H-5), 7.28–7.30 (m, 1H, H-7), 7.27 (s, 1H, H-3), 3.87 (s, 3H, OCH₃), 2.59 (s, 3H, CH₃). ¹³C NMR (150 MHz, CDCl₃): δ 157.1 (C-6), 155.0 (C-2), 143.7 (C-9), 140.0 (C-4), 129.5 (C-8), 124.6 (C-7), 122.0 (C-10), 121.1 (C-3), 100.7 (C-5), 54.6 (OCH₃), 23.7 (CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₁H₁₁ClNO⁺, 208.0524, found, 208.0524.

4.1.4 4-Chloro-2-methylquinolin-6-ol (5). To a cooled (0 °C) solution of 4-chloro-6-methoxy-2-methylquinoline (4) (24.3 mmol, 5.0 g) in CH₂Cl₂ (50.0 mL) was added dropwise BBr₃ (26.6 mL, 26.6 mmol, 1 M in CH₂Cl₂) under argon atmosphere. The reaction mixture was then allowed to warm to room temperature and stirred for 4 h. The solvent was then condensed and the residue was slowly quenched with saturated aqueous NaHCO₃ solution. The precipitate was filtered and washed with water to give 5 as an off-white solid (3.4 g, 72.5%). ¹H NMR (600 MHz, DMSO-d₆): δ 10.28 (s, 1H, OH), 7.85 (d, $J = 9.7$ Hz, 1H, H-8), 7.56 (s, 1H, H-5), 7.34–7.37 (m, 2H, H-3 and H-7), 2.59 (s, 3H, CH₃). ¹³C NMR (150 MHz, DMSO-d₆): δ 156.6 (C-6), 155.7 (C-2), 143.6 (C-9), 139.4 (C-4), 130.9 (C-8), 125.6 (C-7), 123.3 (C-10), 122.4 (C-3), 104.7 (C-5), 24.6 (CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₀H₁₀ClNO⁺, 194.0367, found, 194.0368.

4.1.5 4-Chloro-6-ethoxy-2-methylquinoline (6a). A mixture of 4-chloro-2-methylquinolin-6-ol 5 (5.7 mmol, 1.1 g), bromoethane (10.3 mmol, 1.6 g) and potassium carbonate (17.1 mmol, 2.4 g) in DMF (25.0 mL) was stirred at 40 °C for 4 h. The reaction mixture was filtered and the filtrate was concentrated *in vacuo*. The residue was purified by column chromatography with

petroleum ether/ethyl acetate (4 : 1) to afford 6a as a white solid (1.2 g, 93.6%). ¹H NMR (600 MHz, CDCl₃): δ 8.02 (d, $J = 9.5$ Hz, 1H, H-8), 7.39–7.42 (m, 2H, H-5 and H-7), 7.38 (s, 1H, H-3), 4.19 (q, $J = 7.0$ Hz, 2H, OCH₂CH₃), 2.72 (s, 3H, CH₃), 1.51 (t, $J = 7.0$ Hz, 3H, OCH₂CH₃). ¹³C NMR (150 MHz, CDCl₃): δ 157.6 (C-6), 155.7 (C-2), 144.0 (C-9), 141.4 (C-4), 130.1 (C-8), 125.7 (C-7), 123.5 (C-10), 122.1 (C-3), 102.4 (C-5), 64.0 (OCH₂CH₃), 24.5 (CH₃), 14.7 (OCH₂CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₂H₁₃ClNO⁺, 222.0680, found, 222.0681.

4.1.6 4-Chloro-6-isopropoxy-2-methylquinoline (6b). A mixture of 4-chloro-2-methylquinolin-6-ol 5 (20.7 mmol, 4.0 g), 2-bromopropane (41.4 mmol, 5.1 g) and potassium carbonate (62.1 mmol, 8.6 g) in DMF (120.0 mL) was stirred at 40 °C for 4 h. The reaction mixture was filtered and the filtrate was concentrated *in vacuo*. The residue was purified by column chromatography using petroleum ether/ethyl acetate (4 : 1) to afford 6b as a white solid (2.9 g, 59.6%). ¹H NMR (600 MHz, CDCl₃): δ 7.91 (d, $J = 9.2$ Hz, 1H, H-8), 7.43 (d, $J = 2.8$ Hz, 1H, H-5), 7.32–7.36 (m, 2H, H-3 and H-7), 4.71–4.78 (m, 1H, OCH(CH₃)₂), 2.67 (s, 3H, CH₃), 1.43 (s, 3H, OCH(CH₃)₂), 1.42 (s, 3H, OCH(CH₃)₂). ¹³C NMR (150 MHz, CDCl₃): δ 156.4 (C-6), 155.7 (C-2), 143.9 (C-9), 141.3 (C-4), 130.2 (C-8), 125.7 (C-7), 124.1 (C-10), 122.1 (C-3), 104.0 (C-5), 70.4 (OCH(CH₃)₂), 24.5 (CH₃), 21.9 (s, 2C, OCH(CH₃)₂). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₃H₁₅ClNO⁺, 236.0837, found, 236.0837.

4.1.7 General procedure for the synthesis of 4-substituted-aminoquinoline compounds 7a–7w. A mixture of 4-chloroquinoline derivatives (6a–6b, 0.5 mmol), appropriate substituted anilines (0.6 mmol, 1.2 eq.) and 3 drops conc. HC in *n*-butanol (15.0 mL) was stirred at reflux for 8 h. The reaction mixture was cooled to room temperature and the yellow solid formed was filtered, washed with diethyl ether and recrystallized from ethanol to afford the desired product.

4.1.7.1 *N*-(3,4-Dichlorophenyl)-6-methoxy-2-methylquinolin-4-amine (7a). White solid; yield: 35.8%; HPLC purity: 98.9% ($t_R = 21.92$ min); mp: 266–267 °C. ¹H NMR (600 MHz, DMSO-d₆): δ 8.08 (s, 1H, H-5), 7.96 (d, $J = 9.2$ Hz, 1H, H-8), 7.77 (d, $J = 4.2$ Hz, 1H, Ph-H), 7.76 (d, $J = 1.7$ Hz, 1H, Ph-H), 7.58 (dd, $J = 2.6, 9.2$ Hz, 1H, H-7), 7.50 (dd, $J = 2.4, 8.6$ Hz, 1H, Ph-H), 6.89 (s, 1H, H-3), 3.97 (s, 3H, OCH₃), 2.59 (s, 3H, CH₃); ¹³C NMR (150 MHz, DMSO-d₆): δ 157.9 (C-2), 153.9 (C-6), 151.9 (C-4), 151.8 (C-9), 139.2 (C-1'), 132.4 (Ph-C), 132.0 (C-8), 128.3 (Ph-C), 126.6 (Ph-C), 125.0 (C-7), 124.7 (Ph-C), 123.7 (Ph-C), 118.5 (C-10), 103.0 (C-3), 101.9 (C-5), 56.8 (OCH₃), 21.1 (CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₇H₁₅Cl₂N₂O⁺, 333.0556, found, 333.0552.

Other target compounds (7b–7B) were synthesized following the general procedure as described above with the yield of 25.0–86.0%. Their structures were assigned by the spectroscopic data including ¹H NMR, ¹³C NMR, and ESI-HRMS (see 'ESI⁺').

4.1.8 4-((3,4-Dichlorophenyl)amino)-2-methylquinolin-6-ol (8). To a cooled (0 °C) solution of 7a (10.0 mmol, 3.3 g) in CH₂Cl₂ (50.0 mL) was added dropwise BBr₃ (11.1 mL, 11.1 mmol, 1 M in CH₂Cl₂) under argon atmosphere. The reaction mixture was then allowed to warm to room temperature and stirred for 6 h. The solvent was then condensed and the residue was slowly quenched with saturated aqueous NaHCO₃ solution. The precipitate was filtered and washed with water to give 8 as an

off-white solid (2.2 g, 68.0%). ^1H NMR (600 MHz, DMSO- d_6): δ 8.76 (br. s., 1H, OH), 7.69 (d, $J = 9.0$ Hz, 1H, H-8), 7.55 (d, $J = 8.6$ Hz, 1H, Ph-H), 7.47 (s, 1H, Ph-H), 7.40 (s, 1H, H-5), 7.28 (d, $J = 8.4$ Hz, 1H, Ph-H), 7.25 (d, $J = 9.0$ Hz, 1H, H-7), 6.96 (s, 1H, H-3), 2.45 (s, 3H, CH₃). ^{13}C NMR (150 MHz, DMSO- d_6): δ 156.4 (C-2), 153.3 (C-6), 151.9 (C-4), 145.6 (C-9), 139.2 (C-1'), 132.4 (Ph-C), 132.0 (C-8), 128.3 (Ph-C), 126.5 (Ph-C), 124.9 (C-7), 124.7 (Ph-C), 123.3 (Ph-C), 118.9 (C-10), 105.6 (C-3), 101.7 (C-5), 21.0 (CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₆H₁₃Cl₂N₂O⁺, 319.0399, found, 319.0398.

4.1.9 General procedure for the synthesis of 9a–9e (general procedure for the alkylation of phenols). A mixture of 4-(3,4-dichlorobenzyl)-2-methylquinolin-6-ol (**8**) (1.0 mmol), appropriate alkyl halides (1.1 mmol), and potassium carbonate (331 mg, 2.4 mmol) in DMF (6.0 mL) was stirred at 40 °C for 4 h. The reaction mixture was filtered and the filtrate was concentrated *in vacuo*. The residue was purified by column chromatography using appropriate mixtures of ethyl acetate and petroleum to yield the titled compound.

4.1.9.1 N-(3,4-Dichlorophenyl)-2-methyl-6-propoxyquinolin-4-amine (9a). White solid; yield: 30.0%; HPLC purity: 96.1% ($t_R = 23.96$ min); mp: 266–267 °C. ^1H NMR (600 MHz, DMSO- d_6): δ 7.77 (d, $J = 9.2$ Hz, 1H, H-8), 7.69 (d, $J = 2.0$ Hz, 1H, H-5), 7.63 (d, $J = 8.6$ Hz, 1H, Ph-H), 7.58 (d, $J = 2.4$ Hz, 1H, Ph-H), 7.36–7.40 (m, 2H), 6.94 (s, 1H, H-3), 4.08 (t, $J = 6.5$ Hz, 2H, OCH₂), 2.49 (s, 3H, CH₃), 1.81 (sxt, $J = 7.0$ Hz, 2H, OCH₂CH₂CH₃), 1.03 (t, $J = 7.3$ Hz, 3H, OCH₂CH₂CH₃); ^{13}C NMR (150 MHz, DMSO- d_6): δ 156.2 (C-2), 155.9 (C-6), 147.1 (C-4), 143.0 (C-9), 141.7 (C-1'), 132.1 (Ph-C), 131.6 (C-8), 129.1 (Ph-C), 125.0 (C-7), 123.5 (Ph-C), 122.3 (Ph-C), 121.9 (Ph-C), 119.6 (C-10), 103.7 (C-3), 102.5 (C-5), 70.0 (OCH₂), 24.4 (OCH₂CH₂CH₃), 22.5 (C-11), 11.0 (OCH₂CH₂CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₁₉H₁₉Cl₂N₂O⁺, 361.0869, found, 361.0865.

Other target compounds (**9b–9e**) were synthesized following the general procedure as described above with the yield of 30.0–55.0%. Their structures were assigned by the spectroscopic data including ^1H NMR, ^{13}C NMR, and ESI-HRMS (see 'ESI⁺').

4.1.10 General procedure for the synthesis of 10a–10d (hydrolysis). A mixture of 4-(3,4-dichlorobenzyl)-2-methylquinolin-6-ol (**8**) (1.0 mmol), various lengths of ethyl or methyl bromoalkanoate (1.1 mmol), and potassium carbonate (331 mg, 2.4 mmol) in acetone (10.0 mL) was stirred at 40 °C for 4 h. The reaction mixture was filtered and the filtrate was concentrated *in vacuo*. The residue was purified by column chromatography using appropriate mixtures of ethyl acetate and petroleum to yield the titled compound.

4.1.10.1 Methyl 6-((4-((3,4-dichlorophenyl)amino)-2-methylquinolin-6-yl)oxy)hexanoate (10c). White solid; yield: 64.2%; HPLC purity: 93.3% ($t_R = 24.35$ min); mp: 129–131 °C. ^1H NMR (600 MHz, CDCl₃): δ 7.90 (d, $J = 9.2$ Hz, 1H, H-8), 7.44 (d, $J = 8.6$ Hz, 1H, Ar-H), 7.38 (d, $J = 2.6$ Hz, 1H, H-5), 7.30–7.33 (m, 1H, H-7), 7.13–7.17 (m, 2H, Ar-H), 6.92 (s, 1H, H-3), 3.96–4.04 (m, 2H, 12-CH₂), 3.68 (s, 3H, COO-CH₃), 2.58 (s, 3H, 11-CH₃), 2.34–2.41 (m, 2H), 1.81–1.85 (m, 2H), 1.69–1.73 (m, 2H), 1.47–1.54 (m, 2H); ^{13}C NMR (150 MHz, CDCl₃): δ 173.3 (C=O), 155.7 (C-2), 155.3 (C-6), 145.0 (C-4), 143.4 (C-9), 139.7 (C-1'), 132.2 (Ph-C), 130.0 (C-8), 129.2 (Ph-C), 125.5 (C-7), 121.9 (Ph-C), 120.9 (Ph-C), 119.7 (C-

10), 118.5 (Ph-C), 103.5 (C-3), 99.4 (C-5), 67.0 (C-12), 50.6 (COO-CH₃), 32.9, 27.7, 24.5, 23.5 (C-11). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₂₃H₂₅Cl₂N₂O₃⁺, 447.1237, found, 447.1236.

4.1.10.2 Ethyl 7-((4-((3,4-dichlorophenyl)amino)-2-methylquinolin-6-yl)oxy)heptanoate (10d). White solid; yield: 59.1%; HPLC purity: 96.4% ($t_R = 25.76$ min); mp: 129–132 °C. ^1H NMR (600 MHz, CDCl₃): δ 7.90 (d, $J = 9.2$ Hz, 1H, H-8), 7.43 (d, $J = 8.6$ Hz, 1H, Ph-H), 7.37 (d, $J = 2.4$ Hz, 1H, H-5), 7.31 (dd, $J = 2.6, 9.2$ Hz, 1H, H-7), 7.17–7.20 (m, 1H, Ph-H), 7.14 (dd, $J = 2.5, 8.5$ Hz, 1H, Ph-H), 6.91 (s, 1H, H-3), 4.12 (q, $J = 7.0$ Hz, 2H, COO-CH₂CH₃), 3.98 (t, $J = 6.4$ Hz, 2H, 12-CH₂), 2.58 (s, 3H, 11-CH₃), 2.28–2.35 (m, 2H), 1.79–1.82 (m, 2H), 1.66 (quin, $J = 7.5$ Hz, 2H), 1.43–1.51 (m, 2H), 1.35–1.42 (m, 2H), 1.25 (t, $J = 7.2$ Hz, 1H, COO-CH₂CH₃); ^{13}C NMR (150 MHz, CDCl₃): δ 174.0 (C=O), 156.7 (C-2), 156.5 (C-6), 146.0 (C-4), 144.4 (C-9), 140.7 (C-1'), 133.3 (Ph-C), 131.1 (C-8), 130.3 (Ph-C), 126.6 (C-7), 123.0 (Ph-C), 121.8 (Ph-C), 120.8 (Ph-C), 119.5 (C-10), 104.5 (C-3), 100.2 (C-5), 68.2 (C-12), 60.4 (COO-CH₂CH₃), 34.2, 28.8, 28.7, 25.6, 25.1, 24.8 (C-11), 14.2 (COO-CH₂CH₃). ESI-HRMS (+): m/z [M + H]⁺ calculated for C₂₅H₂₉Cl₂N₂O₃⁺, 475.1550, found, 475.1549.

Other target compounds (**10a–10b**) were synthesized following the general procedure as described above with the yield of 34.0–64.0%. Their structures were assigned by the spectroscopic data including ^1H NMR, ^{13}C NMR, and ESI-HRMS (see 'ESI⁺').

4.1.11 General procedure for the synthesis of 11a–11d. To a solution of **10a–10d** (0.5 mmol) in EtOH (5.0 mL) was added a 20% aqueous NaOH solution and the reaction mixture was stirred at room temperature for 1 h. The mixture was neutralized by the addition of a 10.0% aqueous HCl solution. The resulting precipitate was filtered, washed with diethyl ether and recrystallized from ethanol to afford the corresponding carboxylic acid compound.

4.1.11.1 4-((4-((3,4-dichlorophenyl)amino)-2-methylquinolin-6-yl)oxy) butanoic acid (11a). White solid; yield: 70.0%; HPLC purity: 97.0% ($t_R = 21.99$ min); mp: 266–267 °C. ^1H NMR (600 MHz, DMSO- d_6): δ 7.79 (d, $J = 9.2$ Hz, 1H, H-8), 7.72 (d, $J = 2.4$ Hz, 1H, H-5), 7.65 (d, $J = 8.8$ Hz, 1H, Ph-H), 7.59 (d, $J = 2.6$ Hz, 1H, Ph-H), 7.39 (td, $J = 2.2, 8.8$ Hz, 2H, H-7 and H-6'), 6.93 (s, 1H, H-3), 4.14 (t, $J = 6.4$ Hz, 2H, 12-CH₂), 2.49 (s, 3H, CH₃), 2.45 (t, $J = 7.2$ Hz, 2H, 14-CH₂), 2.03 (quin, $J = 6.8$ Hz, 2H, 13-CH₂); ^{13}C NMR (150 MHz, DMSO- d_6): δ 174.6 (C=O), 156.2 (C-2), 155.8 (C-6), 147.7 (C-4), 142.1 (C-9), 141.3 (C-1'), 132.1 (Ph-C), 131.7 (C-8), 128.4 (Ph-C), 125.5 (C-7), 124.0 (Ph-C), 122.7 (Ph-C), 122.4 (Ph-C), 119.3 (C-10), 103.3 (C-3), 102.5 (C-5), 67.7 (OCH₂), 30.6 (CH₂-COOH), 24.7 (OCH₂CH₂), 24.0 (C-11). ESI-HRMS (–): m/z [M – H][–] calculated for C₂₀H₁₇Cl₂N₂O₃[–], 403.0622, found, 403.0618.

Other target compounds (**11b–11d**) were synthesized following the general procedure as described above with the yield of 70.0–91.0%. Their structures were assigned by the spectroscopic data including ^1H NMR, ^{13}C NMR, and ESI-HRMS (see 'ESI⁺').

4.1.12 General procedure for the synthesis of 12a–12d from their corresponding esters. The appropriate esters **10a–10d** (0.2 mmol), NaOH (2.3 mmol) and hydroxylamine solution (6.9 mmol) was added to DCM/CH₃OH = 1 : 2 (2.0 mL/4.0 mL) at 0 °C. The reaction mixture was warmed to room temperature

and stirred at 25 °C for 24 h. After completion of the reaction (monitored by TLC), the mixture was neutralized with acetic acid. The formed precipitate was collected by filtration, washed with water and recrystallized from ethanol to give the crude product. The crude was purified by column chromatography using appropriate mixtures of dichloromethane and methanol to yield the titled compound.

4.1.12.1 6-((4-((3,4-dichlorophenyl)amino)-2-methylquinolin-6-yl)oxy)-*N*-hydroxy-hexanamide (**12c**). White solid; yield: 50.1%; HPLC purity: 97.9% ($t_R = 22.09$ min); mp: 266–267 °C. ^1H NMR (600 MHz, CD_3OD): δ 7.70 (d, $J = 9.2$ Hz, 1H, H-8), 7.65 (d, $J = 2.4$ Hz, 1H, H-5), 7.54 (d, $J = 8.6$ Hz, 1H, Ph-H), 7.52 (d, $J = 2.6$ Hz, 1H, Ph-H), 7.41 (dd, $J = 2.5, 9.3$ Hz, 1H, H-7), 7.30 (dd, $J = 2.4, 8.6$ Hz, 1H, Ph-H), 6.75 (s, 1H, H-3), 4.07 (t, $J = 6.3$ Hz, 2H, 12- CH_2), 2.48 (s, 3H, CH_3), 2.05 (t, $J = 7.3$ Hz, 2H, 16- CH_2), 1.74–1.85 (m, 2H, 13- CH_2), 1.62 (quin, $J = 7.6$ Hz, 2H, 15- CH_2), 1.43–1.51 (m, 2H, 14- CH_2); ^{13}C NMR (150 MHz, CD_3OD): δ 171.4 (C=O), 157.7 (C-2), 153.9 (C-6), 151.8 (C-4), 138.7 (C-9), 136.9 (C-1'), 133.0 (Ph-C), 131.3 (C-8), 129.1 (Ph-C), 125.8 (C-7), 124.4 (Ph-C), 123.8 (Ph-C), 123.4 (Ph-C), 118.3 (C-10), 101.7 (C-3), 101.2 (C-5), 68.3 (C-12), 32.3 (C-16), 28.4 (C-13), 25.2 (C-15), 25.0 (C-14), 20.1 (C-11). ESI-HRMS (–): m/z $[\text{M} - \text{H}]^-$ calculated for $\text{C}_{22}\text{H}_{22}\text{Cl}_2\text{N}_3\text{O}_3^-$, 446.1044, found, 446.1040.

4.1.12.2 7-((4-((3,4-Dichlorophenyl)amino)-2-methylquinolin-6-yl)oxy)-*N*-hydroxy-heptanamide (**12d**). White solid; yield: 64.9%; HPLC purity: 98.4% ($t_R = 22.76$ min); mp: 266–267 °C. ^1H NMR (600 MHz, $\text{DMSO}-d_6$): δ 7.72 (d, $J = 9.0$ Hz, 1H, H-8), 7.68 (d, $J = 2.6$ Hz, 1H, H-5), 7.59 (d, $J = 0.9$ Hz, 1H, Ph-H), 7.58 (d, $J = 4.8$ Hz, 1H, Ph-H), 7.38 (dd, $J = 2.5, 8.7$ Hz, 1H, Ph-H), 7.30 (dd, $J = 2.6, 9.2$ Hz, 1H, H-7), 6.96 (s, 1H, H-3), 4.11 (t, $J = 6.4$ Hz, 2H, H-12), 2.46 (s, 3H, CH_3), 2.17 (t, $J = 7.2$ Hz, 2H, H-17), 1.74–1.82 (m, 2H, H-13), 1.52 (quin, $J = 7.4$ Hz, 2H, H-16), 1.45 (quin, $J = 7.5$ Hz, 2H, H-14), 1.31–1.39 (m, 2H, H-13); ^{13}C NMR (150 MHz, $\text{DMSO}-d_6$): δ 169.6 (C=O), 157.1 (C-2), 154.1 (C-6), 153.0 (C-4), 139.7 (C-9), 138.2 (C-1'), 134.3 (Ph-C), 131.8 (C-8), 130.3 (Ph-C), 125.6 (C-7), 125.1 (Ph-C), 124.4 (Ph-C), 122.7 (Ph-C), 118.6 (C-10), 103.4 (C-3), 100.3 (C-5), 69.0 (C-12), 49.1 (C-17), 32.7 (C-13), 28.8 (C-15), 25.8 (C-16), 25.5 (C-14), 20.6 (C-11). ESI-HRMS (–): m/z $[\text{M} - \text{H}]^-$ calculated for $\text{C}_{23}\text{H}_{24}\text{Cl}_2\text{N}_3\text{O}_3^-$, 426.1200, found, 426.1197.

Other target compounds (**12a–12b**) were synthesized following the general procedure as described above with the yield of 35.0–65.0%. Their structures were assigned by the spectroscopic data including ^1H NMR, ^{13}C NMR, and ESI-HRMS (see 'ESI†').

4.2. Biological assays

4.2.1 Reagents, antibody and cell lines. SAHA, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazoliumbromide (MTT) and DMSO were purchased from MedChemExpress. The anti-acetylated histone H3 and H4 antibodies were from Santa Cruz Biotechnology. The horseradish peroxidase (HRP) conjugated secondary antibodies were obtained from Thermo Fisher Scientific and the antibodies against α -tubulin (T6074), polymerase (Parp) (9542) and Flag (F1804) were from sigma. The rabbit polyclonal anti-HEXIM1, -CDK9, and -LARP7 antibodies

have been described previously.^{58,59} All the cell lines used in this study were either purchased from American Type Culture Collection (ATCC, Manassas, VA) or described as previously.⁴⁷

4.2.2 Cell culture. J-Lat A2 and 2D10 cells were cultured in 1640 medium (Life Technological) with 10% fetal bovine serum and kept in a CO_2 incubator which consisted of a humidified atmosphere of 5% CO_2 at 37 °C. All the cancer cells (HeLa, A549, NH1, NH2 and HepG2) were grown in DMEM medium (Life Technological) with 10% fetal bovine serum in a humidified atmosphere containing 5% CO_2 at 37 °C.

4.2.3 Flow cytometry screening. The Flow cytometry screening assay was performed in Jurkat-based cells line (J-Lat A2) containing LTR-Tat-IRES-GFP-LTR⁴⁴ and 2D10 cells harboring the nearly complete HIV-1 genome except for the nef gene that is replaced by the GFP-coding sequence.⁴⁵ After incubation with the indicated compounds or 0.1% dimethyl sulfoxide (DMSO) as negative control, cells were harvested and washed twice with 1× phosphate buffered saline (PBS) and analyzed the expression of GFP by flow cytometer (Epics Altra, BECKMAN COULTER).

4.2.4 Luciferase assay. The luciferase assay was conducted in NH1 and NH2, a pair of HeLa-based isogenic cell lines, both of which contain an integrated HIV-1 LTR-luciferase reporter gene but only the latter stably expresses HIV-1 Tat.^{47,51} Cells in twelve-well plate were treated with different concentration of **12c**, **12d** or DMSO for 24 h, then the cell lysates were normalized and measured luciferase activity using luciferase kit from Promega.

4.2.5 Western blotting. Equal amounts of the lysates were electrophoresed on 8% SDS-PAGE gel and transferred to PVDF membranes (0.22 μM). The membranes were blocked with 5% nonfat milk in TBST (50 mM Tris-HCl, pH 7.4, 150.0 mM NaCl and 0.1% Tween 20) buffer for 1 h at room temperature and incubated with various primary antibodies overnight at 4 °C. After three TBST washes, the membranes were incubated with HRP-conjugated anti-mouse or anti-rabbit antibody for 2 h at room temperature. The final immunoreactive products were detected with an enhanced chemiluminescence (ECL) system.

4.2.6 Co-immunoprecipitation. The co-immunoprecipitation assay was performed as described with minor modifications.⁶⁰ Briefly, to detect the dissociation of 7SK snRNP after compounds treatment, nuclear extracts (NEs) were made from F1C2 cells, a HeLa-based cell line stably expressing CDK9-Flag.⁵⁹ One day later, the cells were treated with 5 μM **12c**, **12d** or DMSO as a control for 24 h and then subjected to the preparation of NEs. For anti-Flag IP, NEs were incubated with anti-Flag agarose beads (sigma) for 4 h at a ratio of 10 μL beads per 100 μL NEs. After extensive washing, the eluted proteins were analyzed by western blotting with the indicated antibodies.

4.2.7 Statistical analysis. The data were expressed as mean \pm SD. Each assay was repeated in triplicate in three independent experiments. Statistical significance of differences between groups was analysed by using Student's *t*-test or analysis of variance. $P < 0.05$ was considered significant.

4.3. Molecular modeling

X-ray protein structure of human HDAC2 (PDB code: 4LXZ) was download from Protein Data Bank (PDB) and prepared

with Protein Preparation Wizard panel as implemented in Maestro 10.5 (Schrödinger Release 2016-1: Maestro, Schrödinger, LLC, New York, NY, 2016.). Missing hydrogens and residues were added, bond orders were assigned, and water molecules beyond 5 Å to inhibitor were removed. Both the native ligand SAHA and compound **12c** were prepared with LigPrep panel with OPLS2005 force field, generating the protonation and tautomeric states at 7.0 ± 2.0 pH units. The glide grid center was setting according the geometrical center of original inhibitor (SAHA) and the grid size was $20 \times 20 \times 20 \text{ \AA}^3$, in which the metal coordination was set for Zn^{2+} in the binding site. Prior to docking compound **12c**, a re-docking run was performed to evaluate the docking performance of Glide extra precision (Glide XP) mode. Glide XP mode (Schrödinger Release 2016-1: Glide, Schrödinger, LLC, New York, NY, 2017.) was successful in reproducing the binding mode of native ligand SAHA with a RMSD value of 0.773 Å. Then based on this docking grid, all inhibitors including the co-crystal ligand SAHA were docked flexibly by Glide 7.0 in extra precision with default options.

Conflicts of interest
