Synthesis and structural elucidation of a dehydrochloromethyltestosterone metabolite†

Nicolas Kratena,^a Sarah M. Pilz,^a Matthias Weil,^b Günter Gmeiner,^c Valentin S. Enev^{*a} and Peter Gärtner^{*a}

The human urinary long-term metabolite "M3" (4-chloro-17 β -hydroxymethyl-17 α -methyl-18-norandrost-13-en-3-ol) of the common doping agent DHCMT has thus far been detected *via* GC/MS-MS, creating ambiguities concerning its absolute configuration. Its structure was elucidated *via* the synthesis of all eight possible stereoisomers with 17 β -hydroxymethyl configuration. The highlights of the synthesis consist of a novel first generation approach to 4 β -chloro-5 β compounds as well as a divergent route which allows easy access to the remaining A-ring chlorohydrins.

Introduction

In doping control analysis, a tool with still increasing importance is high sophisticated mass spectrometry MS (HRMS or tandem MS) coupled either to an HPLC or a GC separation system.¹ Due to a lack of structural information, especially in complex organic substances, it is often not possible to completely assign the configuration of *in vivo* formed stereogenic centers using these methods. In order to unambiguously identify the compound or its metabolites in an athlete's sample, the chemical synthesis of the target compound followed by analytical characterization is a suitable method.

A novel long-term metabolite, adapted by the World Anti-Doping Agency (WADA) for testing in 2013 extended the window of detection for dehydrochloromethyltestosterone (DHCMT, **2**) significantly to an estimated time frame of 40–50 days. This resulted in a significant increase in the number of adverse analytical findings for DHCMT in 2013 (1 to 87).² The responsible metabolite M3 (**1**) (4-chloro-17 β -hydroxymethyl-17 α -methyl-18-norandrost-13-en-3-ol) was first detected and described by Sobolevsky and Rodchenkov in 2012.³ The metabolic transformations leading to this metabolite are full A-ring hydrogenation, Wagner–Meerwein-rearrangement and hydroxylation (or *vice versa*). It was assumed that the metab-

olite would be reduced *in vivo* forming a 5 β -androstane, and the authors also argued that the C-3 hydroxyl should be α since 3 β -steroids tend to be excreted as sulphate conjugates.⁴

The stereochemistry at C-4 was left unmentioned on, but the literature suggests the formation of an equatorial 4 β -chloride.⁵ The identity of the compound is not ensured and a reference material provided by organic synthesis would be beneficial for method development and substantially facilitate assay characterization efforts.

In order to prove the identity of the metabolite and elucidate the unknown stereochemistry we planned the synthesis of the most probable target, 4 β -chloro-17 β -hydroxymethyl-17 α -methyl-18-nor-5 β -androst-13-en-3 α -ol (**3a**). In continuation of previous work on long-term metabolites with the 17-hydroxymethyl-17-methyl-18-nor-13-en fragment⁶ we herein report the synthesis of eight possible stereoisomers of compound **1** concerning configurations at C-3, C-4 and C-5 (see Fig. 1).

Retrosynthetic analysis

The retrosynthetic analysis of **3a** is depicted in Scheme 1 and starts with a Wagner–Meerwein-rearrangement to install the functionalities at the D-ring. Epoxide **11** can conceivably be formed from the corresponding C-17 *exo*-methylene, which might be obtained by the reduction of chloroketone **6**. It is known that 3-keto-5 β androstanes are kinetically deprotonated at C-4 regioselectively,⁷ so ketone **5** would be suited for chlorine introduction. The 3-keto-5 β structural motif might come from α,β -unsaturated ketone which is a known intermediate from another metabolite synthesis.

For Route B, the retrosynthesis of the D-ring is as described above. The *trans/trans*-chlorohydrins could be constructed from the C-3-axial epoxides. If epoxide **17** can be accessed, a *trans* addition of the nucleophile⁸ would deliver the desired product, given the reaction proceeds under the right regioselectivity. The epoxides could be synthesized from the corresponding olefins. The literature precedence indicated straightforward access to these olefins *via* the Clemmensen reduction of an α,β -unsaturated ketone which can be derived from dehydroepiandrosterone acetate (DHEA acetate), a commercially available starting material. Inversion of the C-3 can be achieved by oxidation/reduction or a Mitsunobu reaction. To reach the *trans/cis* and *cis/cis* isomers of the 5 α series a suitable 3-keto-4 β -chloro intermediate needs to be epimerised.

Results and discussion

1st generation approach (Route A)

The starting material for this sequence, enone **4**, was synthesized in 6 steps with an overall yield of 40% from DHEA acetate (Scheme 2).^{6a} The chemoselective hydrogenation of the double bond in conjugation was achieved by organocatalytic

Scheme 2 Synthesis of **3a** and **3b** with 1st generation approach: (a) D-CSA, Hantzsch ester, (*S*)-(2-pyrrolidinylmethyl)pyrrolidine, CH₃CN, 70 °C; (b) LiHMDS, THF, NCS, -70 °C; (c) NaBH₄, MeOH, rt; (d) *m*-CPBA, CH₂Cl₂, rt; (e) H₃PO₄, THF/H₂O 2/1, rt.

transfer hydrogenation.⁹ The exocyclic double bond was not touched and ketone **5** was isolated as a 10 : 1 diastereomeric mixture favouring the desired 5 β -product. Next, introducing the chloride through enolate chemistry was investigated and it was found that treating the lithium enolate of **5** with *N*-chlorosuccinimide (NCS) yields the 4 β -chloro product **6** as a single diastereomer in 61% yield.

All other approaches (silyl enol ethers or other sources of electrophilic chlorine) failed or gave complex mixtures. At this stage, the structure of compound **6** was confirmed *via* single crystal X-ray diffraction to ascertain C-4, C-5 configuration.

Next, the reduction of **6** (sodium borohydride) gave a 1 : 1 mixture of alcohols which after separation yielded **7** and **8** in a ratio of 1 : 1.3. The epoxidation of these olefins with *m*-CPBA gives 17 α -epoxy as major (**10**, **12**, not shown in the scheme) and 17 β -epoxy as minor (**9**, **11**) products, and the latter were isolated in 25–30% yield. The following rearrangement was carried out with the 17 β -epoxides only, since they possess the right stereoelectronic prerequisites.^{6b} Accordingly, epoxides **9** and **11** were treated with phosphoric acid to give the first two putative metabolites **3a** (*trans* product: $J_{H3-H4} = 9.6$ Hz) and **3b** (*cis* product: $J_{H3-H4} = 2.7$ Hz) in 43% and 28% isolated yield, respectively. Additionally, 3 β configuration in **7** which yielded **3b** was confirmed by a reduction experiment of **6** with L-Selectride® which is known to give exclusively cyclohexanols with an axial hydroxyl group by the equatorial delivery of the hydride.

After the first two putative metabolites showed some differences in compound **1** found in excretion studies, the synthesis of the remaining stereoisomers was attempted. A number of approaches for the synthesis of 4 α -chloro-5 β compounds were unsuccessful (epimerisation, inversion *via* substitution, hydrogenation of a chloroalkenyl). Ultimately, the divergent synthesis outlined in Scheme 1 (Route B) was pursued.

Scheme 1 Retrosynthetic analysis of compound **3a** and divergent route.

2nd generation approach (Route B)

As depicted in Scheme 3, the divergent synthesis started with already known alcohol **13** (2 steps, 80%, from DHEA acetate)^{6a} which was oxidized under Oppenauer conditions to give diketone **14** in 91% yield. Subjecting this diketone to excess zinc in acetic acid rapidly reduces the A-ring enone to an olefin¹⁰ giving rise to a new stereocenter at C-5 in a 1.3 : 1 ratio favouring the 5 α isomer. The separation of the diastereomers **15** and **16** was not practical at this stage, instead the mixture of olefins was epoxidized with *m*-CPBA to give compounds **17** and **18** as the only two diastereomers. The epoxides were then treated with concentrated hydrochloric acid and gave a mixture of isomeric chlorohydrins **19**, **20** and **21**. While for the 5 α -isomer the opening proceeded with distinct regioselectivity, for the 5 β -isomer both possible regioisomers were observed. The separation of this three-component mixture was achieved with column chromatography and chlorohydrins **19**, **20** and **21** were isolated in 14%, 19% and 42% yield (over three steps). The configuration and stereochemistry of diastereomer **19** were proved by single crystal X-ray determination. The undesired chlorohydrin **20** can be recycled to pure **18** by treatment with a strong base.¹¹ Likewise chlorohydrin **21** was used to obtain a pure analytical sample of **17**.

Chlorohydrins **19** and **21**, if further elaborated, can lead to four new putative metabolites (*vide infra* Schemes 4 and 5). The last two of the eight possible diastereomers in this series are the 4 α -chloro-5 α compounds. These were obtained by the oxidation of **21** with DMP (Dess–Martin periodinane) and treatment of the resulting diketone **22** with potassium hydroxide, which effected complete C-4 epimerisation over two steps to give **23** in 94% yield.

Its structure was also confirmed by single-crystal XRD. A reduction affecting only the C-3 ketone was needed and it was found that Meerwein–Ponndorf–Verley reduction results in a 1 : 1 mixture of C-3 epimeric alcohols **24** and **25** in 84% yield, which were separated and provides the starting point for the synthesis of the last two potential metabolites.

The synthesis from this point forward is the same for all four chlorohydrins and is discussed in detail for **21**. First, the alcohol is protected as a TBS ether (**26**) and subsequently treated with the Nysted reagent¹² and titanium tetrachloride to give *exo*-methylene product **28**. The double-bond is epoxidized with *m*-CPBA to give a 2 : 1 mixture of diastereomers (major product **37**; *vide infra* Fig. 2) of which again only the minor product **36** was used. The Wagner–Meerwein-rearrangement was initiated by trimethylsilyl triflate/2,6-lutidine in dichloromethane or toluene at low temperatures.¹³ This method offers a slight increase in isolated yield compared to the aqueous acidic rearrangement protocol used before (typically 45–55%). Finally, the TBS ether in **42** is cleaved with hydrochloric acid in methanol to furnish the final *trans* ($J_{\text{H}3-\text{H}4} = 2.61$ Hz) product **3c**. To arrive at the C-3 epimer global oxidation with DMP, followed by NaBH₄ reduction, furnished the equatorial *cis* ($J_{\text{H}3-\text{H}4} = 2.78$ Hz) alcohol **3d**.

This sequence was also carried out for the previously mentioned chlorohydrins: 19, 24 ($J_{\text{H}3-\text{H}4} = 9.2$ Hz) and 25, giving the isomers 3e–h and completing the synthesis of eight possible isomeric 4-chloro-17 β -hydroxymethyl-17 α -methyl-18-nor-androst-13-en-3-ols (see Schemes 5–7; compounds 27, 35, 39, 41, and 45 not depicted). Single crystal X-ray analysis of 25 and 37 was performed to secure structural information on the stereochemistry of the A-ring substituents and the 17-spiroepoxides. The molecular structures resulting from the previously mentioned XRD experiments are depicted in Fig. 2.

Conclusions

To summarise, we have accomplished the first synthesis of the reported long-term metabolite “M3” of dehydrochloromethyl-testosterone. All possible eight stereoisomers 3a–3h of this material have been synthesized using two different synthetic routes. A straightforward, short approach and a highly divergent second approach, which can deliver all eight stereoisomers from a common precursor, were developed. GC-MS/MS analysis of the products and their comparison with excretion studies of DHCMT have been performed in the laboratories of our collaborators and the identity of 3h was proved (4 α -chloro-17 β -hydroxymethyl-17 α -methyl-18-nor-5 α -androst-13-en-3 α -ol) with the *in vivo* metabolite of DHCMT. Details of these studies have been submitted for publication elsewhere.¹⁴

Experimental section

General

Dehydroepiandrosterone was purchased from FluoroChem. Dry toluene, dichloromethane, dimethylformamide and *m*-CPBA are from Acros Organics. HPLC grade solvents (acetonitrile, methanol, isopropanol) were from VWR. All other non-specified chemicals were from Sigma-Aldrich. Anhydrous tetrahydrofuran was pre-dried using an Innovative Technologies PureSolv system, degassed and stored under 3 Å molecular sieves. NMR spectra were recorded on a Bruker AC400 and AC600 using TMS as an internal standard. IR spectra were recorded on a PerkinElmer Spectrum 65 using thin films (ATR FT-IR). TLC-analysis was performed with pre-coated aluminium-backed plates (Silica gel 60 F254, Merck). Compounds were visualized by submerging in an acidic phosphomolybdic acid/cerium sulphate solution and heating. Melting points were determined with a Kofler hot-stage apparatus. HR-MS analysis was carried out from acetonitrile solutions (concentration: 10 ppm) by using an HTC PAL system autosampler, an Agilent 1100/1200 HPLC with binary pumps, a degasser and a column thermostat and an Agilent 6230 AJS ESI-TOF mass spectrometer.

For single crystal X-ray diffraction analysis, crystals were embedded in perfluorinated polyether and mounted on MITGEN™ loops. X-ray diffraction data were obtained in a cold stream of nitrogen at $T = 100$ K on a Bruker APEX-II diffr-

actometer with Mo-K α radiation. The collection strategy for the measurement was optimized with APEX-2 using ω - and φ -scans. After the integration of the data with SAINT, a semi-empirical absorption correction was performed with SADABS. The crystal structures were solved by direct methods and refined using the SHELXTL program package. All H atoms were placed geometrically and refined in a riding model approximation. The H atoms of hydroxyl groups were taken from difference maps and refined freely. Crystallographic data for the structure(s) reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC 1586619–1586622 and 1825768.†

General procedure A: epoxidation with *m*-CPBA

The olefin is dissolved in CH₂Cl₂ (0.05–0.1 M), and KHCO₃ (3 eq.) and *m*-CPBA (1.25 eq.) are added in this order. The reaction mixture is stirred at room temperature for 1–3 h and quenched by the addition of water and saturated Na₂S₂O₃ solution. The biphasic mixture is transferred to a separatory funnel and is shaken vigorously. The aqueous phase is extracted 3 times with CH₂Cl₂ and the pooled organic phases are washed with brine and dried over MgSO₄. The crude product after evaporation is purified by column chromatography (60 : 1 silica : product) using LP/EtOAc mixtures as the eluent system. The 17 α -epoxy compound is obtained as the major and the desired 17 β -epoxy is obtained as the minor product in all instances.

General procedure B: epoxide formation with base

The chlorohydrin starting material is dissolved in methanol (0.1 M) and solid KOH (5 eq.) is added. The base is dissolved by stirring and after a clear solution has been formed the mixture is heated to reflux for 10 hours. After cooling of the reaction mixture half the volume of saturated NH₄Cl solution and half the volume water are added, and the solution is transferred to a separatory funnel. This is extracted twice with CH₂Cl₂ and the organic phases are combined, washed with brine and dried over MgSO₄. The crude product can be purified by recrystallization from *n*-heptane.

General procedure C: TBS protection

The chlorohydrin starting material is dissolved in dry DMF (0.3 M) at room temperature and imidazole (2.5 eq.) and TBSCl (1.3 eq.) are added. The reaction mixture is stirred at room temperature for 5–96 h and is then evaporated to dryness *in vacuo*. The solid residue is taken up in EtOAc and 0.2 M HCl. The phases are shaken in a separatory funnel and the aqueous phase is extracted twice with small portions of EtOAc. The pooled organic phases are washed with saturated NaHCO₃ solution and brine and dried over MgSO₄. After evaporating the solvent the crude product is purified *via* flash chromatography (10 : 1 silica : product).

General procedure D: Nysted methylation

A Schlenk flask under an argon atmosphere was charged with Nysted reagent suspension (20 wt%, 5 eq.), which is diluted

with half the volume of dry THF. The milky suspension is chilled to 0 °C in an ice-bath and TiCl₄ (neat, 2.2 eq.) is added dropwise. The suspension is stirred for 10 minutes before removing the ice-bath and allowed to warm to room temperature. After 5 minutes the starting material dissolved in dry THF is added dropwise to the darkening suspension. After the addition is complete the flask is sealed and stirred for 14–20 hours (overnight). The reaction mixture is then poured onto a 1/1 mixture ice/2 M HCl and diluted by adding the same volume of Et₂O. This is transferred to a separatory funnel and the mixture is shaken vigorously. After the separation of the phases the aqueous phase is extracted three times with Et₂O and the combined organic phases are washed with saturated NaHCO₃ solution, followed by brine and drying over MgSO₄. After evaporation the crude product is purified *via* flash column chromatography on silica (15 : 1) using 10/1 → 3/1 LP/CH₂Cl₂ as the eluent.

General procedure E: Wagner–Meerwein rearrangement

A Schlenk flask under an argon atmosphere was charged with dry CH₂Cl₂ or toluene (0.05 M) and the solvent is cooled to –78 °C. Then 2,6-lutidine (2.5 eq.) and TMSOTf (2 eq.) are added at that temperature. After five minutes, the starting material is dissolved in CH₂Cl₂ or toluene and added dropwise to the chilled reaction mixture. The reaction mixture is stirred at –78 °C for 1 hour and then quenched by the addition of the same volume of methanol followed by 2 M HCl (10 eq.). The reaction vessel is taken out of the cooling bath and stirred at room temperature for 30 minutes. The mixture is then transferred to a separatory funnel and diluted with water and CH₂Cl₂. After the separation of the phases the aqueous phase is extracted twice with CH₂Cl₂ and the pooled organic phases are washed with saturated NaHCO₃ solution and dried over MgSO₄. The crude product obtained after evaporation is purified by column chromatography on silica (70 : 1) using between 10/1 and 5/1 LP/EtOAc as the eluent.

Cleavage of the TBS protecting group was observed under these conditions in some cases.

General procedure F: TBS deprotection

The starting material was fully dissolved in the smallest possible amount of methanol (*ca.* 0.1 M) and 2 M HCl (5 eq.) was added. The resulting solution was stirred at room temperature for 20–96 h. After the reaction is complete saturated NaHCO₃ solution is added and the methanol is evaporated *in vacuo*. The reaction mixture is then extracted with CH₂Cl₂, and the extracts are combined and dried over MgSO₄ and filtered over a small pad of silica (*ca.* 1 g). Evaporation of the solvent affords the product.

Epoxide **11** (30 mg, 0.088 mmol, 1 eq.) was dissolved in a mixture of 2/1 THF/water (4 ml) and 0.1 ml concentrated H₃PO₄ and stirred at room temperature until TLC showed full conversion. The solution was then diluted with water, and

extracted three times with small portions of CH_2Cl_2 . These extracts were washed with brine and dried over MgSO_4 . The crude product (45 mg) was purified over a silica gel column with 8/1 LP/EtOAc as the eluent to give 13 mg (43%) of diol **3a** as foam.

13 α -Androst-4-en-3,17-dione (14)

A 500 mL round bottom flask was charged with 1.5 g 3 β -hydroxy-13 α -androst-5-en-17-one⁷ (**13**) (5.2 mmol, 1 eq.), 250 ml dry toluene and 10.75 ml cyclohexanone (104 mmol, 20 eq.). The solution was heated to reflux and after 15 minutes 2.65 g aluminium isopropoxide (13 mmol, 2.5 eq.) were added, upon which the solution turned yellow. After refluxing for 1 hour, the reaction was complete and was allowed to cool to room temperature. The mixture was then washed with 50 ml 0.1 M H_2SO_4 twice and once with saturated NaHCO_3 solution and brine. After drying over MgSO_4 and evaporating the volatiles the product was left to crystallize at 4 °C overnight. The crystals (390 mg) were filtered, and washed with small amounts of LP. The mother liquor was concentrated and purified on 55 g silica gel using 2/1 LP/EtOAc as the eluent. In total 1.36 g of diketone **14** (91%) were obtained as colorless needles.

Analytical data were in accordance with the literature.¹⁵

13 α ,5 ξ -Androst-3-en-17-one (15, 16)

A 250 ml round bottom flask was charged with 50 ml acetic acid and 2.85 g diketone **14** and heated to reflux. Zinc (20.15 g, 0.3 mol, 31 eq.) was added in portions over 25 minutes. The reaction was complete after the addition and was allowed to cool. The solids were filtered and washed thoroughly with ethyl acetate (100 ml). The filtrate was evaporated to dryness and taken up in CH_2Cl_2 and washed with water (25 ml). The aqueous phase was extracted once with 25 ml CH_2Cl_2 and the combined organic phases were dried over MgSO_4 and evaporated to dryness. The crude mixture of ketones **15** and **16** (1.3 : 1 dr, 2.61 g, 96%, determined *via* $^1\text{H-NMR}$) was used directly in the next step.

3 ξ ,4 ξ -Epoxy-13 α ,5 ξ -androst-17-one (17, 18)

The mixture of **15** and **16** (2.61 g, 9.6 mmol) from the previous step was dissolved in CH_2Cl_2 (100 ml) in a 250 ml round bottom flask. To this solution 2.02 g KHCO_3 (19.2 mmol, 2 eq.) as well as 2.6 g *meta*-chloroperbenzoic acid (10.5 mmol, 1.1 eq.) were added over 5 minutes and the resulting suspension was stirred at room temperature for 1.5 hours. The reaction was flooded with NaHCO_3 and $\text{Na}_2\text{S}_2\text{O}_3$ solutions (25 ml each)

and extracted with CH_2Cl_2 . The combined organic phases were washed once with small portions of water and brine (10 ml) and dried over MgSO_4 . After evaporating and drying under high vacuum 2.83 g of crude epoxides **17** and **18** (102% yield, approx. 95% purity) were obtained. These were used in the next step directly.

Analytical samples were obtained by the treatment of isolated chlorohydrins **20** and **21** according to general procedure B.

3 ξ -Hydroxy-4 ξ -chloro-5 ξ ,13 α -androstan-17-one (19, 20, 21)

The isomeric mixture of epoxides **17** and **18** (2.83 g, 9.8 mmol, 1 eq.) was charged in a 250 ml round bottom flask and dissolved in 50 ml chloroform. 25 ml concentrated HCl (32%, 29 g, 254 mmol, 26 eq.) were added over the course of 5 minutes and the resulting biphasic mixture was stirred vigorously. After 30 minutes, the solution was transferred to a separatory funnel and the phases were separated. The aqueous phase was extracted with 25 ml CH_2Cl_2 and the pooled organic phases were washed with saturated NaHCO_3 solution and brine. The extracts were dried over MgSO_4 and evaporated. The residue was purified on silica gel (100:1) using 40/40/1 LP/ CH_2Cl_2 / CH_3CN and subsequently recrystallized from *n*-heptane or diisopropylether to give 445 mg 5 β -isomer **19** (14%), 600 mg chlorohydrin **20** (19%), and 1.33 g of 5 α -isomer **21** (42%).

140 ml methanol and 1.4 g of crude product **22** (4.34 mmol, 1 eq.) were charged in a 250 ml round bottom flask. At room temperature, 2.43 ml of a 10% solution of KOH was added in methanol (4.34 mmol, 1 eq.) dropwise. The solution turned yellow when the addition was complete and was stirred for 5 minutes, followed by 1 ml of acetic acid to neutralize. The reaction mixture was concentrated *in vacuo* and the resulting white precipitate was dissolved in water/CH₂Cl₂ and after shaking, the aqueous phase was again extracted twice with CH₂Cl₂. The pooled organic phases were washed with NaHCO₃ solution and brine and dried over MgSO₄. The crude product obtained after evaporating the solvent was purified on silica (60 g) using 10/1 to 4/1 LP/EtOAc as the eluent. 1.31 g (94%) of diketone **23** was obtained as a fine microcrystalline solid.

4 α -Chloro-17 α -methyl-18-nor-3-oxo-5 β -androst-13-en-17 β -carbaldehyde (45)

In a 50 ml round bottom flask alcohol 3e (21 mg, 0.062 mmol, 1 eq.) was dissolved in 6 ml CH_2Cl_2 at room temperature and DMP ($\text{C}_{13}\text{H}_{13}\text{IO}_8$, 79 mg, 0.19 mmol, 3 eq.) was added in one portion and the solution was stirred for 20 minutes. The reaction mixture was then washed with NaHCO_3 solution followed by $\text{Na}_2\text{S}_2\text{O}_3$ solution and the organic phase was dried over MgSO_4 and evaporated to dryness. The compound decomposes (epimerizes) on silica gel, so the crude product was instead used directly in the next step.

4 β -Chloro-17 α -methyl-18-nor-3-oxo-5 α -androst-13-en-17 β -carbaldehyde (46)

In a 25 ml round bottom flask alcohol 3c (30 mg, 0.088 mmol, 1 eq.) was dissolved in 7 ml CH_2Cl_2 at room temperature and DMP (112 mg, 0.26 mmol, 3 eq.) was added in one portion and the solution was stirred for 60 minutes. The reaction mixture was then washed with NaHCO_3 solution followed by $\text{Na}_2\text{S}_2\text{O}_3$ solution and the organic phase was dried over MgSO_4 and evaporated to dryness. The crude product was purified by chromatography on silica gel (2.5 g) using 25/1 LP/EtOAc as the eluent giving 21 mg (71%) aldehyde 46 as small crystals.
