Metal-free borylative dearomatization of indoles: exploring the divergent reactivity of aminoborane C–H borylation catalysts†

Arumugam Jayaraman,^{ID} Luis C. Misal Castro,^{ID} Vincent Desrosiers^{ID} and Frédéric-Georges Fontaine^{ID}*

While the dearomatization of indoles by carbon–boron bond forming reactions is new and quite promising, they are so far mainly metal-catalyzed. Here, we establish the use of metal-free catalysts in promoting such reactions in an atom-efficient way. The *in situ* generated ambiphilic aminoborane catalyst (1-Pip-2-BH₂-C₆H₄)₂ (Pip = piperidyl) promotes borylative dearomatization of various 1-arylsulfonyl indoles with pinacolborane in a *syn* addition fashion, with H and Bpin groups added respectively to the 2 and 3 positions of indoles. Catalysis proceeds with good to excellent conversion and essentially with complete regio- and diastereoselectivity. From mechanistic insights and DFT computations, we realized and established that prototypical boranes can also catalyze this borylative dearomatization.

Dearomative functionalization of indoles is of high interest for synthetic chemists and chemical industries to generate the structural motifs of numerous pharmaceuticals, natural products, and materials (Fig. 1).¹ While this approach appears more reasonable in terms of the number of synthetic steps, achieving it is usually hard due to the strong aromatic resonance delocalization in heteroarenes,² which disfavors the kinetics and thermodynamics of dearomatization.^{2,3} Despite this hurdle, many methods have been developed in recent years to operate these transformations.⁴ Dearomatization with the introduction of a boron-containing moiety is attractive since organoboron products with a C_(sp³)–B bond can readily serve as coupling partners in a variety of metal-catalyzed cross coupling reactions⁵ and in the emerging metal-free coupling reactions.⁶ Some examples of stoichiometric and catalytic borylative dearomatization of heteroarenes, mostly pyridine derivatives, have been reported.⁷ Notably, Rh(i),^{7f} Mg(II)^{7a} and La(III)^{7c} complexes (Scheme 1a) and boron-based species have been used as catalysts.^{7e} In all these stoichiometric and catalytic reactions, dearomatization occurs as a result of the 1,2-addition of H and Bpin groups with boron typically adding to the nitrogen atom of pyridines. In 2015, Ito and co-workers reported the borylative dearomatization of N-protected indoles with bis(pinacolato) diboron using Cu(i) catalysts,⁸ which forms C–B bonds and

affords regio-, diastereo- and enantioselective 3-borylated indolines with the H and Bpin groups added respectively at the 2 and 3 positions in an anti-fashion (Scheme 1a).

In the same year, we described a novel metal-free approach for the borylation of unactivated electron-rich heteroarenes, using pinacolborane (HBpin) as the reagent and ambiphilic aminoborane (1-TMP-2-BH₂-C₆H₄)₂ (1, TMP = 2,2,6,6-tetramethylpiperidine, Scheme 1b) as the catalyst.⁹ The primary mechanistic step of this approach is the concerted C–H activation of heteroarenes by the ambiphilic aminoborane catalyst using the concept of frustrated Lewis pair (FLP) chemistry.¹⁰

Although the transition metal-free borylation of heteroarenes using electrophilic boron reagents was already known,¹¹

Scheme 1 Catalytic borylation and borylative dearomatization reactions of heteroarenes: (a) previous studies on catalytic borylative dearomatization of heteroarenes, (b) our previous work on the B/N FLP catalyzed C–H borylation reaction, and (c) this work on B/N FLP catalyzed borylative dearomatization of indoles. EDG = electron donating group; Cp* = pentamethylcyclopentadienyl; Cbz = benzyloxycarbonyl.

additional metal-free systems for the borylation reaction appeared in the literature after our report.^{4e,12} We subsequently showed that the bench-stable fluoroborate salt of 1,1-TMP(H)-2-BF₃-C₆H₄ (**1F**), can be used as a precatalyst for this reaction.¹³ Recently, we have expanded this new borylation methodology by designing more active ambiphilic aminoborane catalysts (2–4, Scheme 1b).¹⁴ We wish to report here that while covering a wide variety of heteroarenes, some heterocycles undergo borylative dearomatization rather than borylation through C–H activation. Indeed, the *syn* addition and borylative dearomatization of indoles are catalyzed by *in situ* generated metal-free ambiphilic aminoborane catalysts (Scheme 1c). From the mechanistic insights rationalizing the preference of the FLP catalysts for either activation modes, we demonstrate that prototypical boranes of the form BH₃·base can also catalyze the same borylative dearomatization reaction. Our metal-free approach

Scheme 2 Borylative dearomatization of 1-tosyl indole catalyzed by *in situ* generated ambiphilic aminoboranes. Ts = SO₂(C₆H₄CH₃).

towards this transformation is atom-efficient and essentially provides regio- and diastereoselective products in good to excellent yields.

Although compounds **1**–**4** catalyze exclusively the C–H borylation of 1-methyl indole in presence of HBpin, we observed that the substrate 1-tosyl indole rather undergoes a divergent route by performing borylative dearomatization, installing the H and Bpin moieties respectively at the 2- and 3-positions (Scheme 2). Although all four *in situ* generated ambiphilic aminoboranes catalyze the borylative dearomatization of 1-tosyl indole, we chose to use the piperidine-based precatalyst **2F** for further exploration, as its preparation is more convenient. As shown in Table 1, treatment of 1-tosyl indole with 1.3 equiv. of HBpin and 5 mol% of **2F** in CDCl₃ at 100 °C resulted in the formation of borylative dearomatized product **6a** with 67% conversion after 16 h (entry 2). As expected, this reaction does not proceed in the absence of a precatalyst (entry 1). Increasing the precatalyst and HBpin loadings to 10 mol% and 1.5 equiv., respectively, and decreasing the reaction time to 6 h provided again a moderate conversion (entry 3). However, extending the reaction time to 16 h gave a conversion of 99% (entry 4). Although most experiments were carried out in CDCl₃, it is possible to change the solvent to THF and 2-Me-THF (entries 5 and 6).

Interestingly, this reaction comes to completion under neat conditions in less than 12 hours (entry 7). While the conversion is still taking place, albeit in significantly lower yields, in the presence of benzoic acid, dimethylaniline, and benzonitrile as additives, no product was observed in the presence of phenol, acetophenone and ethyl benzoate additives (see the ESI†).

Next, the scope of this catalytic C–B bond forming borylative dearomatization reaction using different 1-arylsulfonyl indoles

Table 1 Initial results and reaction optimization

Entry	2F (mol%)	HBpin (equiv.)	Conditions ^a	Conv ^b (%)
1	0	1.1	CDCl ₃ , 100 °C, 24 h	0
2	5	1.3	CDCl ₃ , 100 °C, 16 h	67
3	10	1.5	CDCl ₃ , 100 °C, 6 h	62
4	10	1.5	CDCl ₃ , 100 °C, 16 h	99

6	10	1.5	2-MeTHF, 100 °C, 16 h	95
7	10	1.5	Neat, 100 °C, 12 h	99

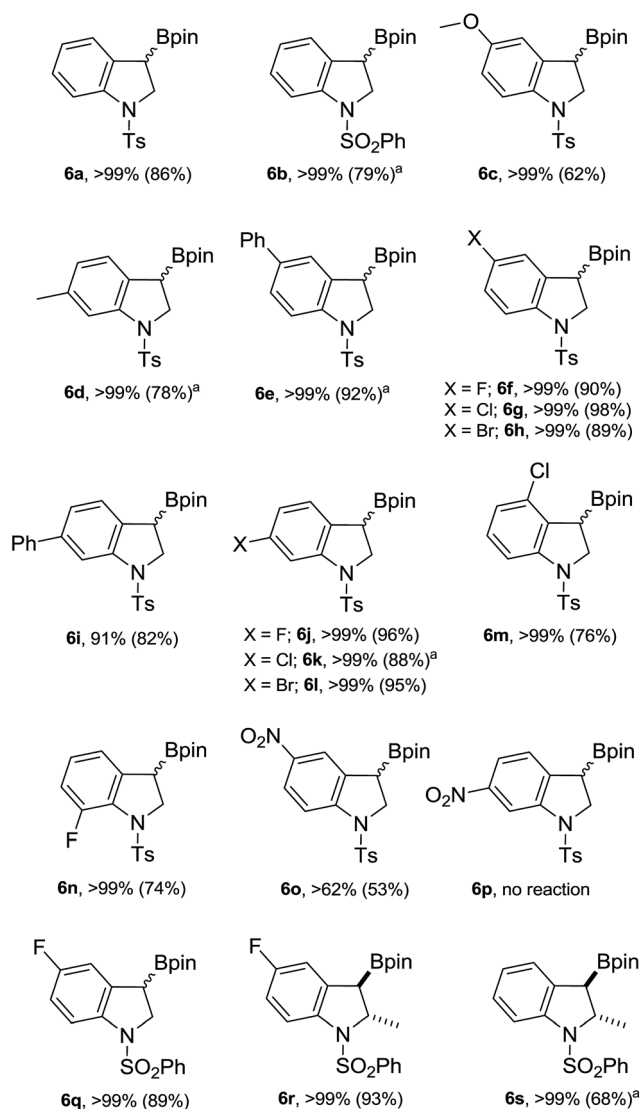

^a Reaction temperature used is 100 °C. ^b Percent conversions are ¹H NMR conversions determined with an aliquot vs. hexamethylbenzene as internal standard.

was examined (Scheme 3). The 1-tosyl indoles with either electron-donating or electron-withdrawing functionalities at the 4- or 5-position undergo the borylative dearomatization reaction across the C2–C3 aromatic double bond with a high regioselectivity and good-to-excellent conversions (**6c**, **6e–6h**, **6m**, and **6o**). Likewise, the 1-tosyl indoles possessing the methyl (**6d**), phenyl (**6i**), fluoro (**6j**), chloro (**6k**), or bromo (**6l**) substituents at the C6-position were well tolerated. In contrast, the electron-withdrawing nitro substituent at the C6-position of the 1-tosyl indole did not allow borylative dearomatization (**6p**). While it is possible to catalytically hydroborate 5-nitro-1-tosyl indole (**6o**) with a moderate conversion, the absence of reaction with 6-nitro-1-tosyl indole suggests that the strong electron withdrawing effect, combined with the negative inductive effect ($-I$) and negative mesomeric effect ($-M$), exerted by the nitro group

on the *para*-positioned C3 carbon, is shutting down this process. Some of the formed hydroborated products are unstable under the routine workup procedure or in the presence of silica gel, and thus were subsequently oxidized to the corresponding alcohols using the commercially available household bleach comprised of 6% NaOCl, which is known to oxidize organoboranes stereoretentively.¹⁵ In some cases, the oxidized products were further functionalized with silyl protecting groups. The highly regioselective borylative dearomatization of different 1-arylsulfonyl indoles achieved using an ambiphilic aminoborane catalyst tempted us to disclose the diastereoselectivity of this metal-free approach. This was probed using 5-fluoro-2-methyl-1-phenylsulfonyl indole and 2-methyl-1-phenylsulfonyl indole substrates. Catalysis under optimal conditions afforded the *syn* addition products **6r** and **6s**, respectively, having the Bpin and methyl substituents positioned *trans* to each other. A strong support of the *syn* addition of H and Bpin groups comes from the X-ray crystallographic characterization of product **6r** (Fig. 2, left). In the case of 2-methyl-1-phenylsulfonyl indole, the product **6s** is less stable; therefore, it was derivatized to 2-methyl 3-siloxy 1-phenylsulfonyl indoline **6s''** using the stereoretentive oxidant NaOCl (household bleach) and silylating reagent TBDMSCl. The X-ray crystallographic characterization of product **6s''**, as depicted in Fig. 2 (right), clearly indicates the formation of a *syn* addition product (**6s**).

Notably, in the framework of transition metal catalysis and organocatalysis, this is the first catalytic method for borylative dearomatization of indoles which ensures addition in a *syn* fashion. Moreover, this metal-free methodology can be considered complementary to the existing group 10 metal-catalyzed borylative dearomatization of 1-Cbz indoles (Cbz = benzyloxycarbonyl) in which the H and Bpin groups are added in an anti-fashion.⁸ Our observation and generalization of borylative dearomatization of 1-arylsulfonyl indoles using the same catalyst that can catalyze C–H borylation of electron-rich heteroarenes demonstrates the divergent ability of our catalytic system. The divergent ability of our catalysts also includes the recent report on S–H borylation of thiols.¹⁶ Because the synthesis of precatalyst **2F** is expedient and the catalytic conversions are quantitative in most cases, we have demonstrated that this metal-free catalysis can be applied to gram-

Scheme 3 Scope of 1-arylsulfonyl indoles. Reaction conditions: 1-arylsulfonyl indoles (0.5–1.0 mmol), precatalyst **2F** (10–20 mol%), HBpin (1.5–2.6 equiv), 100 °C, CDCl₃/neat, 16–24 h. The numbers in parentheses are the isolated yield. ^aIndicates the isolated yield after oxidation.

scale synthesis, *via* preparing **6a** in 2 grams from **5a** under neat conditions.

A plausible mechanism for the borylative dearomatization reaction is shown in Scheme 4.¹⁷ The initial step of this catalytic cycle involves cleavage of the dimeric catalyst. The active monomeric catalyst then undergoes hydroboration with the substrate, which leads to the formation of the 3-borylated intermediate (**A1**), a possible resting state in the catalytic cycle. The σ -bond metathesis between the $C_{(sp^3)}-B$ bond of **A1** and the H-B bond of HBpin, as observed in the catalyzed $C_{(sp^3)}-H$ borylation of heteroarenes, is unlikely since our computational attempts to optimize the corresponding transition state using catalyst **4** led to the dissociation of HBpin from **A1**. Thus, we propose that the redistribution of the backbone leads to the product and regeneration of our catalyst. Several precedents of redistribution reactions between RBH_2 and $R'B(OR'')_2$ have been reported (*vide infra*).¹⁸

To investigate the proposed initial hydroboration step and to compare it with the possible C-H activation, the activation barriers were computed, using the model chemistry $\omega B97XD/6-311G+**/PCM_{(chloroform)}/\omega B97XD/6-311G+**$ (ref. 19) as implemented in the Gaussian 09 package,²⁰ with the dimethyl catalyst **4**. Computations show a barrier of 25.9 kcal mol⁻¹ for the hydroboration of 1-phenylsulfonyl indole while the C-H activation step is higher in energy at 27.8 kcal mol⁻¹, suggesting that the former mechanism is favored by 1.9 kcal mol⁻¹ (Fig. 3, top). In the case of more electron-rich 1-methyl indole, the C-H activation is preferred over hydroboration as the barrier for activation is lower by about 5.2 kcal mol⁻¹ (Fig. 3, bottom), which is in accordance with our experimental observations.⁹ Since the hydroborated intermediate **A1** is 2.8 kcal mol⁻¹ higher

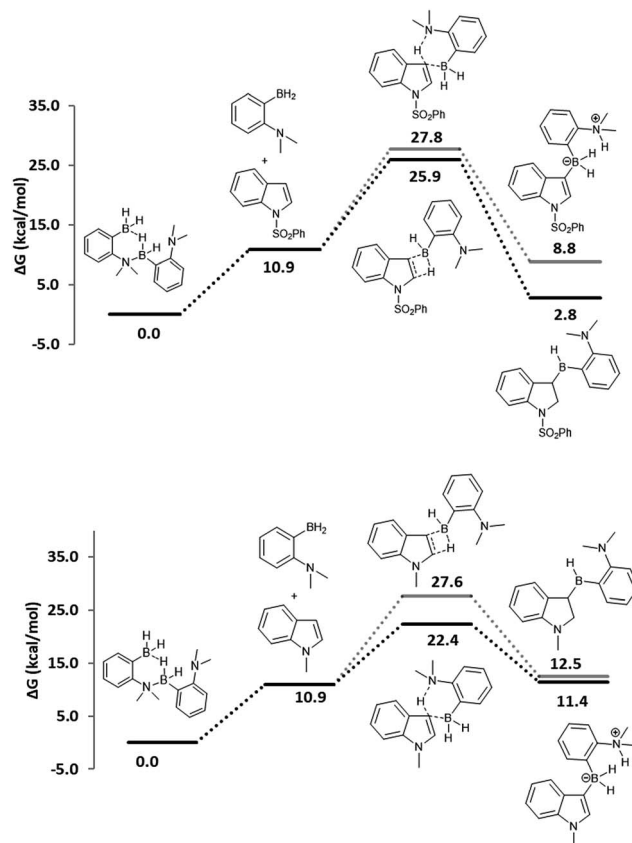

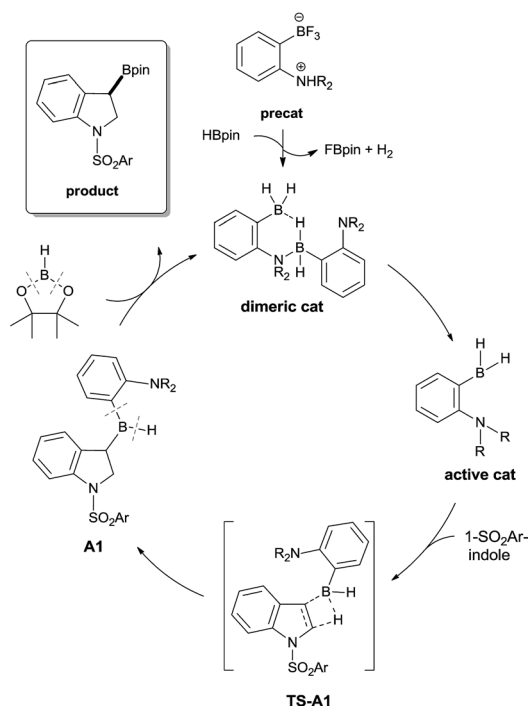

Fig. 3 DFT computed free energy profiles for hydroboration vs. C-H activation of 1-phenylsulfonyl indole (top) and 1-methyl indole (bottom) by the ambiphilic aminoborane catalyst **4**.

Scheme 4 Plausible mechanism for the ambiphilic aminoborane catalyzed borylative dearomatization.

in energy compared to the starting materials, this intermediate was not observed experimentally. Indeed, ¹H NMR and ESI mass spectrometry of the CDCl₃ solution of equimolar catalyst **2** and 1-tosyl- or 1-phenylsulfonyl indole showed only unreacted starting material and no detectable intermediate was seen when the solution was heated at 100 °C for 16 h. These results suggest that the catalytic hydroboration is a competing reaction for the catalytic borylation reaction. Hydroboration dominates when the aromatic π -delocalization in heteroarenes is significantly reduced, and the borylation, through C-H activation, dominates when the π -delocalization is intact or enhanced. This difference in the reactivity pattern explains how our ambiphilic aminoboranes show a divergent catalytic activity according to the nature of the 1-substitution on indoles.^{9,14}

As the computational evidence suggests that the amino group is not required for catalysis, we next proceeded with simple primary and secondary boranes not having an ambiphilic character. Catalysis did not occur when using only catecholborane (HBcat) or the simple phenylborane, generated *in situ* from tetrabutylammonium trifluoro(phenyl)borate. Surprisingly, the prototypical boranes $BH_3 \cdot$ base, often reflected as a "trojan horse" in catalytic or stoichiometric hydroboration reactions,^{18,21} catalyze the borylative dearomatization quantitatively with no change in the regio- and diastereoselectivity (Scheme 5). Further optimization of this approach using many

Scheme 5 Borylative dearomatization of indoles catalyzed by prototypical boranes.

different BH_3 adducts revealed that the $\text{BH}_3 \cdot \text{DMS}$ (dimethyl sulfide) and $\text{BH}_3 \cdot \text{THF}$ (tetrahydrofuran) adducts are the more efficient catalysts (see Table S2 of the ESI[†]), as the reaction slowly proceeds even at room temperature. At 100 °C, the reaction comes to completion within 1 h, which is much faster than that observed for all other examined BH_3 adducts and aminoborane catalysts. Next, the group of substrates that was successfully transformed using precatalyst **2F** was examined with the $\text{BH}_3 \cdot \text{DMS}$ catalyst (Table S3 of the ESI[†]). The same selectivity observed using precatalyst **2F** was observed with the exception that BH_3 catalyzes the reaction at lower temperature (60 °C) and faster. To demonstrate the viability of this process, product **6q** was prepared on a two gram-scale using $\text{BH}_3 \cdot \text{DMS}$ as the catalyst. A main advantage of using $\text{BH}_3 \cdot \text{base}$ as catalysts is that the purification of the products is much easier as it involves only evaporation of the catalysts and excess reagents *in vacuo*.

The mechanism proposed for the $\text{BH}_3 \cdot \text{base}$ catalyzed transformation is shown in Fig. 4 and is identical to the one depicted in Scheme 4 for the aminoborane catalysts. Computations show that the initial hydroboration step is exergonic, leading to the formation of hydroborated BH_2 dimer, **B2** (−8.9 kcal mol^{−1}), which is in equilibrium with the monomeric dimethyl sulfide adduct **B2'** (−5.6 kcal mol^{−1}). The unprotected monomeric form **B2''** is much higher in energy (8.1 kcal mol^{−1}). This was demonstrated using NMR spectroscopy, where we observed that the stoichiometric reaction of $\text{BH}_3 \cdot \text{DMS}$ with 1-phenylsulfonyl indole at 60 °C for 16 h led to a single

hydroboration product in equilibrium between the borane-dimethylsulfide adduct and the diborane dimer. As mentioned above, our inability to observe the similar intermediate from the reaction between 1-phenylsulfonylindole and ambiphilic aminoborane catalysts can be rationalized by thermodynamics of this addition step. The DFT results show that the addition is endergonic (2.8 kcal mol^{−1} for catalyst **4**, Fig. 3) for the aminoborane catalyst, while it is exergonic in the case of BH_3 catalysts. In the second step of the mechanism, scrambling of the backbone occurs between this newly formed BH_2 -intermediate (**B2**) and HBpin. The scrambling between hydrides and alkoxy groups between primary boranes and secondary boronic esters is well known.^{18b,22} The first hydride switch leads to the ring-opened intermediate **B3** and is endergonic by 12.9 kcal mol^{−1}, with a rate limiting barrier of 23.7 kcal mol^{−1}. The final step involving the second hydride switch is exergonic by −16.9 kcal mol^{−1} with a barrier of 9.2 kcal mol^{−1}. The direct formation of the final product **B4** from **B2** *via* a direct σ -bond metathesis between the C–B bond of **B2** and the H–B bond of HBpin has a barrier of 34.4 kcal mol^{−1} (not shown, see the ESI[†]); thus, this pathway was considered kinetically uncompetitive in comparison to the backbone redistribution process.

It was recently demonstrated by Thomas and co-workers that a variety of alkenes could undergo hydroboration with HBpin as a reagent and the $\text{BH}_3 \cdot \text{base}$ acting as catalysts.²³ However, the hydroboration of indoles to generate 3-borylindolines is scarce in the scientific literature even if this transformation is synthetically useful for the construction of complex molecular structures for the pharmaceutical industry.²⁴ While protection of sensitive functionalities is required to apply the borylated products in synthetic applications such as for cross-coupling reactions, many mild and efficient deprotection strategies were well documented for the deprotection of the tosyl group after the execution of a desired transformation.²⁵ We should also note that the borylative dearomatized products can also be readily obtained by the stoichiometric hydroboration of tosyl indoles with $\text{BH}_3 \cdot \text{DMS}$ followed by the addition of pinacol, as

Fig. 4 DFT-computed free energies, in kcal mol^{−1}, for the BH_3 catalyzed borylative dearomatization of 1-phenylsulfonyl indole. Species **B2'** is the dimethyl sulfide adduct, and **B2''** is the monomeric form.

Scheme 6 Stoichiometric borylative dearomatization reaction of 1-tosylindole using $\text{BH}_3 \cdot \text{DMS}$ and pinacol. Species $\text{BH}_2\text{-Int}$ likely exists in equilibrium between its DMS adduct and the diborane dimer form.

exemplified here with the 1-tosyl indole substrate in Scheme 6. This route is cheaper relative to the other synthetic routes described herein, but the ability to modify the framework of aminoborane catalysts could potentially lead to asymmetric induction, which prototypical boranes cannot do.

In summary, we have established the catalytic use of a bench-stable precatalyst, 1-Pip(H)-2- $\text{BF}_3 \cdot \text{C}_6\text{H}_4$ (2F), for the C–B bond forming borylative dearomatization of indoles. The *in situ* generated ambiphilic aminoborane catalyzes borylative dearomatization of various 1-arylsulfonyl indoles with HBpin and proceeded in a *syn* addition fashion with a high conversion and with complete regio- and diastereoselectivity. From the mechanistic insights, we recognized and demonstrated that prototypical boranes can also catalyze the same reactions with an improvement in the catalytic efficiency. The metal-free catalytic approach we demonstrated can be considered complementary to the existing transition metal-based catalytic system where an anti-addition of H and Bpin is followed exclusively. Eventhough prototypical boranes are being efficient to catalyze borylative dearomatization of *N*-arylsulfonyl indoles, utilizing ambiphilic aminoboranes as catalysts is still advantageous as they can become chiral catalysts when decorated with chiral substituents and may enable the enantioselective borylative dearomatization reactions. To achieve this, asymmetric ambiphilic borane catalytic systems are currently being developed in our laboratory.

- 17 Other mechanism involving B-H activation of HBpin by aminoborane catalyst followed by delivering the activated HBpin across the C2–C3 double of indole was proposed initially, but later dismissed on the basis of DFT computed high activation barrier for the delivery step (see ESI†).
