# Intrinsic poorly-crystallized $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$ : a highly efficient oxygen evolution reaction electrocatalyst under alkaline conditions†

 Xiaoteng Ding,<sup>‡a</sup> Wei Cui,<sup>‡b</sup> Xiaohua Zhu,<sup>c</sup> Jianwei Zhang<sup>\*d</sup> and Yusheng Niu<sup>id \*a</sup>

As the bottleneck of electrochemical overall water splitting, the oxygen evolution reaction (OER) needs efficient catalysts to lower the required overpotential. Electrocatalysts with an amorphous form are highly active but suffer with low structural stability. Poorly crystallized materials with activity like amorphous forms, while maintaining the mechanical robustness of crystalline forms, are expected to be ideal materials. Towards this direction, we, for the first time, developed low-crystalline  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  as an excellent OER electrocatalyst with an overpotential of 269 mV, in order to drive a current density of  $100 \text{ mA cm}^{-2}$  in a 1.0 M KOH environment, and this outperforms most of the reported Fe-based electrocatalysts. Notably, its activity can be maintained for at least 100 hours. A one-pot synthesis for the poorly-crystallized material using one of the most abundant metal elements to obtain effective OER catalysis will provide great convenience in practical applications.

## Introduction

The ever-increasing depletion of fossil fuels and worsening environmental contamination stimulate extensive research into clean and efficient energy generation systems.<sup>1–3</sup> Among these, electrochemical water splitting has attracted significant attention due to hydrogen production utilizing electricity from renewable but intermittent sources such as solar energy, wind, wave power, *etc.*<sup>4,5</sup> However, the associated energy conversion efficiency is greatly limited by the sluggish oxygen evolution reaction (OER), which is a complex four-electron redox process.<sup>6–9</sup>  $\text{IrO}_2$  and  $\text{RuO}_2$ , as the most efficient electrocatalysts, exhibit high OER activity, yet their low-abundance and high cost dramatically hinder commercial utilization.<sup>10</sup> Alternatives based on earth-abundant and inexpensive transition-metal based materials are actively being pursued.

As non-precious-metal compounds, Fe-based oxides can serve as active OER electrocatalysts, but they are restricted by their low conductivity and chemical stability.<sup>11–16</sup> Highly crystallized Fe nitrides,<sup>17–20</sup> phosphides,<sup>21–23</sup> sulfides,<sup>24</sup> *etc.* have better electronic conductive properties and are more

thermodynamically/chemically stable, exhibiting progressive OER activity. However, their electrocatalytic performances are still far from the requirements of practical applications. A challenging route, the topological transformation strategy towards an amorphous structure, has been developed to improve OER dynamics by increasing the intrinsic activity and exposing more active sites. However, the resulting non-crystallized materials are generally susceptible to unavoidable collapse to some degree, exhibiting unsatisfactory robustness.<sup>25–27</sup> Designing poorly-crystallized materials with excellent catalytic activity similar to the amorphous form, and with structural stabilization of crystallization will provide a fresh and efficient perspective towards an ideal model.

On the basis of the above consideration, low-crystalline  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  was proposed and was developed by a one-pot hydrothermal method in the presence of Ni foam (NF). Such material anchoring on NF ( $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$ ) demonstrates excellent OER activity with an overpotential of 269 mV to drive  $100 \text{ mA cm}^{-2}$  current density in a 1.0 M KOH environment, outperforming most of the reported Fe-based electrocatalysts. More remarkably, its activity can be maintained for at least 100 h. It is shown that the highly efficient electrocatalytic OER performance lies in the unrivaled structure superiority, stemming from the poor-crystallization state that is caused by the existence of massive oxygen-deficiencies.

## Results and discussion

Fig. 1a shows the X-ray diffraction (XRD) pattern of the solvothermally obtained products. The diffraction peaks at  $36.08^\circ$ ,  $40.54^\circ$ ,  $46.43^\circ$ ,  $53.15^\circ$ ,  $61.32^\circ$ , and  $63.02^\circ$  are indexed to the

**Fig. 1** (a) XRD pattern of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$ . (b) XPS survey spectrum of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$ . XPS spectra of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  in the (c) Fe 2p and (d) O 1s regions.

(110), (200), (113), (114), (115), and (106) crystal planes of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$ , respectively (JCPDS No. 29-0712).<sup>28</sup> Moreover, X-ray photoelectron spectroscopy (XPS) characterization was performed on the resulting  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$ . The corresponding XPS survey spectrum (Fig. 1b) provides evidence for the presence of Fe and O elements. The N element should be derived from the adsorbed ferric nitrate impurity.<sup>29</sup> In the Fe 2p region (Fig. 1c), the binding energy (BE) of 709.2 eV can be attributed to the ferric nitrate adsorbed on the  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  nanocrystallites. The peak at 710.2 eV is assigned to the BE of Fe 2p<sub>3/2</sub> in  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$ .<sup>29</sup> Moreover, the peaks centered at 530.4 eV, 531.2 eV, and 533.1 eV in the O 1s region (Fig. 1d) are ascribed to the Fe–O bond, the oxygen vacancies and the hydroxyl group, respectively, in the  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$ .

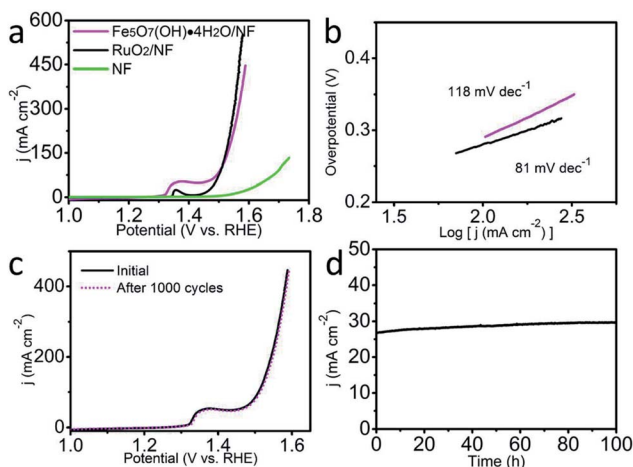

Fig. 2a and b show the scanning electron microscopy (SEM) images of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$ . It can be seen that the  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  nanosheets grow tightly on the NF and form arrays on the NF. The Brunauer–Emmett–Teller (BET) tests revealed that the surface area of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$  is 50.2 cm<sup>2</sup>. The associating transmission electron microscopy (TEM) image of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  further confirms its nanosheet structure (Fig. 2c), and the high-resolution TEM (HRTEM) image demonstrates that the lattice is not well-defined (Fig. 2d), due to its intrinsic poorly-crystallized state. The electron spin resonance (ESR) spectroscopy determination unveils the presence of a surface oxygen vacancy. The obtained samples show two distinct symmetrical ESR signal peaks at  $g = 2.002$  (Fig. S1†). The corresponding selected area electron diffraction (SAED) pattern shows rings indexed to the (115) and (110) planes of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$ . Energy-dispersive X-ray (EDX) elemental mapping images of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$  (Fig. 2e and f) also show that Fe and O elements are uniformly distributed in the  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  product.

The electrochemical OER performance was examined in 1.0 M KOH using a typical three-electrode configuration.

(c) TEM image of one single  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  nanosheet. (d) HRTEM image and SAED pattern for the  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  nanosheet. EDX elemental mapping images of (e) Fe and (f) O.

$\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$  ( $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}$  loading: 0.6 mg cm<sup>-2</sup>) was used as the working electrode, while Hg/HgO (filled with 6 M KOH solution) and a graphite plate were utilized as the reference and counter electrodes, respectively. For comparison, NF and  $\text{RuO}_2$  deposited on NF ( $\text{RuO}_2/\text{NF}$ ,  $\text{RuO}_2$  loading: 0.6 mg cm<sup>-2</sup>) were also tested under the same conditions. Considering ohmic potential drop (*iR*) losses, experimental data were all

**Fig. 3** (a) LSV curves of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$ ,  $\text{RuO}_2/\text{NF}$  and bare NF for OER. (b) Corresponding Tafel plots for  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$  and  $\text{RuO}_2/\text{NF}$ . (c) LSV curves for  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$  before and after 1000 CV cycles. (d) Time-dependent current density curve of  $\text{Fe}_5\text{O}_7(\text{OH}) \cdot 4\text{H}_2\text{O}/\text{NF}$ . All experiments were tested in 1.0 M KOH.

Fig. 4 The amount of oxygen theoretically calculated and experimentally measured versus time for  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  in 1.0 M KOH.

corrected for further analysis, thus directly reflecting the intrinsic behavior of the catalysts. The overpotentials were converted and reported as values vs. the reversible hydrogen electrode (RHE). As observed from the linear sweep voltammetry (LSV) curves in Fig. 3a,  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  demonstrates an outstanding catalytic activity with an overpotential of 269 mV to drive  $100 \text{ mA cm}^{-2}$  in 1.0 M KOH, outperforming most of the reported Fe-based electrocatalysts such as Ni-Fe LDH ( $269 \text{ mV} - 5 \text{ mA cm}^{-2}$ ),<sup>30</sup> Ni-Fe LDH/CNT ( $269 \text{ mV} - 40 \text{ mA cm}^{-2}$ ),<sup>31</sup> FeOOH/Au ( $450 \text{ mV} - 9 \text{ mA cm}^{-2}$ ),<sup>32</sup> etc. (Table S1†). More impressively, such an electrocatalytic performance even surpasses that of  $\text{RuO}_2/\text{NF}$  ( $279 \text{ mV}$ ,  $100 \text{ mA cm}^{-2}$ ). As for the Tafel plots shown in Fig. 3b,  $\text{RuO}_2/\text{NF}$  gives a Tafel slope of  $81 \text{ mV dec}^{-1}$ . The corresponding Tafel slope for  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  ( $118 \text{ mV dec}^{-1}$ ) is relatively larger than that for  $\text{RuO}_2/\text{NF}$ , implying the further engineering requirement towards more favorable catalytic kinetics. The high surface area of the array structure, affirmed by the BET measurements, and the existence of abundant oxygen-defects verified by the electron spin resonance spectrum, both contribute to the outstanding catalytic activity. The intrinsic oxygen-defects of  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}$  result in its poorly-crystallized state. We deliberately treated the sample under high-temperature and the degraded catalytic activity was observed, related to the overpotentials of 280 mV and 480 mV to deliver  $15 \text{ mA cm}^{-2}$  and  $100 \text{ mA cm}^{-2}$ , respectively (Fig. S2†). However, such a performance of the sample after high-temperature treatment is still very attractive for scientific researchers. To further gain insight into the excellent OER activity of  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}$ , we examined the electrochemical double layer capacitances ( $C_{\text{dl}}$ ), proportional to the electrochemical surface area (ECSA), for  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$ . Fig. S3† presents the corresponding cyclic voltammograms. The slope for the linear plot of the non-faradaic capacitance currents as a function of scan rates is the value of  $C_{\text{dl}}$ . The  $C_{\text{dl}}$  for  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  is  $18 \text{ mF cm}^{-2}$ , and ECSA was determined to be  $45 \text{ cm}^2$  on the basis of the equation:  $\text{ECSA} = C_{\text{dl}}/0.4$ . A series of cyclic voltammograms for  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  and  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  after heat treatment were

collected, and are shown in Fig. S4.† A linear plot related to the oxidation currents for the redox species as a function of the scan rates can be obtained from the cyclic voltammograms, and the turnover frequency (TOF) was determined to be  $0.017 \text{ mol of O}_2 \text{ s}^{-1}$  at an overpotential of 269 mV for  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$ , and this is superior to those of samples after heat treatment ( $0.00468 \text{ mol O}_2 \text{ s}^{-1}$  for overpotential of 300 mV). The long-term stability of  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  was also evaluated by continuous cyclic voltammetry scanning at a scan rate of  $100 \text{ mV s}^{-1}$ . After 1000 cycles in 1.0 M KOH, the obtained LSV curve almost coincides with the initial one (Fig. 3c). The superb durability of  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  was also recorded by OER electrolysis at a fixed overpotential, preserving its catalytic activity for at least 100 h (Fig. 3d).

The experimentally emerging gas species was qualitatively determined by gas chromatography analysis and was further qualified using a calibrated pressure sensor, monitoring the pressure change in the anodic compartment of the H-type electrolytic cell. The faradaic efficiency (FE) of  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}/\text{NF}$  was then calculated to be 100% by comparing the molar number of the practically evolved oxygen with the theoretically calculated number (Fig. 4).

## Conclusions

In summary, poorly-crystallized  $\text{Fe}_5\text{O}_7(\text{OH})\cdot 4\text{H}_2\text{O}$  was designed and exploited by a one-pot hydrothermal method as a high-efficiency water-oxidation electrocatalyst. Profiting from its low-crystallization state, such a material exhibits a low overpotential of 269 mV at  $100 \text{ mA cm}^{-2}$  current density, exceeding most of the reported Fe-based electrocatalysts. More encouragingly, the activity can be maintained for at least 100 h. This current work not only provides an outstanding OER electrocatalyst, but also demonstrates a new avenue to construct highly efficient poorly-crystallized catalysts, by a relatively quick method using one of the most abundant metal elements, for other electrocatalytic systems.
