Effective reuse of waste heat energy is an important energy savings issue for green transformation. In general, phase-change heat storage materials cannot store energy for a prolonged period. If a solid material could conserve the accumulated thermal energy and release it only on demand, then its heat-storage application potential is considerably widened. From this angle, in 2015, we proposed the concept of a longterm heat-storage material, in which latent heat is preserved until the material is triggered by an external stimulus. This feature article describes long-term heat-storage ceramics composed of lambda-trititanium-FEATURE ARTICLE<br> **(a)** Check for undates<br>  $\frac{1}{2}$  Check for undates<br>

### 1. Proposal of long-term heat-storage materials for a green transformation

Climate change due to the rise of  $CO<sub>2</sub>$  concentration is a global problem. To safeguard our planet and pass it to the next generation of humanity, it is imperative to develop

 $b$  Department of Materials Science, Faculty of Pure and Applied Sciences, University of Tsukuba, 1-1-1 Tennodai, Tsukuba, Ibaraki 305-8573, Japan. E-mail: tokoro@ims.tsukuba.ac.jp

technologies and green innovation along with the accompanying social transformation, green transformation  $(GX)$ .<sup>1-14</sup> Although producing nature-friendly energy (renewable energy) is vital, effective reuse of the produced energy and further energy savings are also important. From this point of view, we have developed eco-friendly materials (i.e., heatstorage materials). $15,16$  One material effectively reuses energy, while another is suitable for energy-conserving optical recordings.

For GX, reuse of waste heat energy is instrumental. Currently, approximately 40% of the consumed energy from sources such as oil, gas, and coal is released into the atmosphere as waste heat. This causes several negative

Shin-ichi Ohkoshi

Shin-ichi Ohkoshi is a Professor at the Department of Chemistry, School of Science, The University of Tokyo since 2006. He serves as the Project Officer of SPRING GX, JST, Director of the CNRS International Research Laboratory, Visiting Professor of the University of Manchester, and Honorary Member of Magdalen College, University of Oxford. Representatives awards he has received include the CSJ Award (2019) and Humboldt Research Award (2020). His research

interests focus on functional phase transition materials based on metal oxides and metal complexes exhibiting light-induced phase transition, millimeter wave absorption, heat-storage properties, and so on. He has 550 publications and has submitted 300 patents.

Marie Yoshikiyo

Marie Yoshikiyo is an Assistant Professor at the Department of Chemistry, School of Science, the University of Tokyo. She received her BSc in 2011, MSc in 2013, and PhD in 2021 from the Department of Chemistry, School of Science, The University of Tokyo. She became Project Assistant Professor at the Department of Chemistry, School of Science, the University of Tokyo in 2015, and has started her current position in 2022. Her

research interest mainly focuses on the development of functional metal oxides.

environmental effects.<sup>7,8</sup> Approximately 80% of this wasted heat energy is below 200 °C (473 K) (Fig. 1).<sup>17</sup> The development of high-performance heat-storage materials should help solve these problems. Known heat-storage materials include sensible ones such as bricks and concrete and solid–liquid latent heatstorage ones such as water, paraffin, and polyethylene glycol (Fig. 2).<sup>10–15</sup> In general, the heat energy accumulated in a heatstorage material is slowly released over time. The lack of long-term heat storage is known as the ''time-gap problem.'' The ability to store heat long-term and release it on demand opens numerous practical applications.

Recently, we reported a new concept called long-term heatstorage ceramic.<sup>15,16</sup> A long-term heat-storage ceramic can conserve latent heat until the material is activated by an external stimulus. The material is lambda-trititaniumpentoxide ( $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>), which shows a reversible phase transition to beta-trititanium-pentoxide ( $\beta$ -Ti<sub>3</sub>O<sub>5</sub>) by an external stimulus

Jessica MacDougall

Jessica MacDougall received her MChem from Durham University (UK) in 2017, and her MSc in chemistry from the University of Tokyo (Japan) in 2020. She is currently a PhD student in the solid-state physical chemistry laboratory of the Department of Chemistry, School of Science, the University of Tokyo under the supervision of Professor Shinichi Ohkoshi. Her research mainly focuses on functional metal oxide nanoparticles.

Fig. 1 Temperature range vs. the total amount of heat energy for the 38% of input resource energy wasted annually as heat in Japan. Of the wasted heat, 78% of the total caloric value is below 200 °C. such as pressure.  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> also exhibits a reversible photoinduced phase transition between  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> by light irradiation. Moreover,  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> is a promising eco-friendly recording material composed of only common elements.

In this feature article, we describe  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and its metalsubstituted series with potential as long-term heat-storage ceramics. This metal oxide can preserve the accumulated heat energy of the phase transition with  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. Applying external pressure releases the energy on demand. The rest of this article is organized as follows. Section 2 explains the discovery and basic physical properties of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>. Section 3 describes the pressure-induced phase transition and heat-storage property. Section 4 demonstrates the control of the heat-storage property such as the necessary pressure for heat release and the heatstorage temperature. Section 5 discusses two other functionalities: light-induced and current-induced phase transitions. Finally, Section 6 provides the summary and future prospects. Feature Article<br>

### 2. Discovery of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and its physical properties

Titanium oxide, TiO<sub>2</sub>, is a common metal oxide. Tetravalent  $TiO<sub>2</sub>$  is white. It is used as a white pigment for cosmetics or buildings and as a photocatalyst. By contrast, other titanium oxides, including trivalent titanium, show a black color. They are used in black-color cosmetics or as heat-absorbing materials (Fig. 3). The black color originates from the d-electron in the trivalent titanium. Combining the trivalent and tetravalent titanium ions generates various titanium oxides (TiO<sub>2</sub>, Ti<sub>4</sub>O<sub>7</sub>,  $Ti<sub>3</sub>O<sub>5</sub>$ ,  $Ti<sub>2</sub>O<sub>3</sub>$ , etc.), which display a range of colors from white to pitch black.

To discover new materials or functionalities, we investigated titanium oxide nanoparticles. Nanoparticles of white titanium oxide  $(TiO<sub>2</sub>)$  have been intensively studied for various applications such as photocatalysts. Despite their interesting features, nanoparticles of black titanium oxides are less studied. For example, single crystal of  $Ti<sub>3</sub>O<sub>5</sub>$  exhibits a metal-insulator

Fig. 3 Appearance, properties, and valence states of known titanium oxides.

phase transition or an antiferromagnetic transition.<sup>18</sup> Our research focuses on nanoparticle synthesis of  $Ti<sub>3</sub>O<sub>5</sub>$  to elucidate the influence of particle size on the phase transition properties.15,16,19,20

#### Synthesis and morphology of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>

We initially synthesized  $Ti<sub>3</sub>O<sub>5</sub>$  as nanoparticles by the following process.<sup>15</sup> First, nanoparticles were trapped in glass by a combination method of reverse-micelle and sol–gel processes. Then the precursor was sintered under a hydrogen flow to obtain titanium oxide nanoparticles in the glass matrix. Fig. 4(a) shows the transmission electron microscopy (TEM) image of the obtained nanoparticles in the glass matrix. Finally, the glass matrix was chemically etched to obtain the nanoparticles (Fig. 4(a), inset). The powder X-ray diffraction (PXRD) pattern indicated a new monoclinic structure (space group  $C2/m$ ) (Fig. 4(b) and (c)). We discovered this new type of titanium oxide in 2010 and named it ''lambda-trititaniumpentoxide  $(\lambda$ -Ti<sub>3</sub>O<sub>5</sub>)''. ChernComm Vexa are considered on 23 May 2023. Discovering the composition of the published on 23 May 2023. Downloaded to the series are compositely enhanced under a compositely enhanced under a series are compositely the

 $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> shows several types of morphologies, depending on the synthesis. The aforementioned initial synthesis of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> gave nanocrystals in a  $SiO<sub>2</sub>$  matrix. The sol–gel method also produces  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> nanocrystals.<sup>19</sup> The sintering temperature can control the size of the nanocrystals:  $8 \pm 2$  nm for 1123 °C, 9  $\pm$  3 nm for 1133 °C, 9  $\pm$  2 nm for 1143 °C, 10  $\pm$  3 nm for 1153 °C, 11  $\pm$  4 nm for 1163 °C, 13  $\pm$  4 nm for 1173 °C,  $25 \pm 12$  nm for 1200 °C, and 36  $\pm$  15 nm for 1250 °C.

Another synthesis method to prepare large batches of  $\lambda$ - $Ti<sub>3</sub>O<sub>5</sub>$  in fewer steps is to simply sinter anatase-TiO<sub>2</sub> nanoparticles (size = 7 nm) under a hydrogen flow.<sup>15</sup> Fig. 5(a) (upper) shows the scanning electron microscopy (SEM) image of the obtained sample, which has a coral-like morphology with a particle size of 2  $\mu$ m. Fig. 5(a) (lower) shows the TEM image,

Fig. 4 (a) TEM image of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> nanoparticles embedded in the SiO<sub>2</sub> matrix. Inset shows a single nanocrystal. (b) PXRD pattern of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> in  $SiO<sub>2</sub>$  with Rietveld analysis. Red dots, black lines, and blue lines show the observed pattern, calculated pattern, and their difference, respectively. Green bars show the calculated Bragg positions of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>. (c) Crystal structure of monoclinic  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>. Reproduced from ref. 15, copyright 2010 Springer Nature.

Fig. 5 (a) HRTEM image of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> prepared from anatase-TiO<sub>2</sub> and its nanocrystal size distribution. Inset shows the SEM image and the size distribution of flake-form  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>. (b) Temperature dependence of the PXRD pattern between  $31.5^{\circ}$  and  $33.5^{\circ}$ . (c) Temperature dependence of the (2 0 3) peak of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and (0 2 3) peak of  $\alpha$ -Ti<sub>3</sub>O<sub>5</sub>. Reproduced from ref. 15, copyright 2010 Springer Nature.

indicating that the flake-form morphology is an assembly of primary nanocrystals with an average particle size of 25 nm. This approach can yield  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> in large quantities.

PXRD measurements acquired as the temperature is increased show that the diffraction peaks of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> are converted to  $\alpha$ -Ti<sub>3</sub>O<sub>5</sub> peaks continuously, for example (2 0 -3) and  $(2 \t0 \t3)$  of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>  $\rightarrow$   $(0 \t2 \t3)$  of  $\alpha$ -Ti<sub>3</sub>O<sub>5</sub> (Fig. 5(b) and (c)). Furthermore, heating the sample to 640 K and subsequently cooling it to 300 K causes  $\alpha$ -Ti<sub>3</sub>O<sub>5</sub> peaks to return to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> peaks.

#### Magnetic and electric properties

Fig. 6(a) shows the magnetic susceptibility ( $\gamma$ ) versus temperature (T) curve of the flake-form  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and that of a conventional single-crystal  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. The  $\gamma$  value of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> across the measured temperature range remains at  $ca. 2 \times 10^{-4}$  emu per Ti atom, suggesting that  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> is a Pauli paramagnet due to metallic conduction. The estimated electrical conductivity  $(\sigma)$ value for  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> is 30 S cm<sup>-1</sup>, indicating that it is a near metallic conductor. This is consistent with the magnetic data. Fig. 6(b) shows the ultraviolet-visible (UV-vis) and infrared (IR) reflectance spectra.  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> exhibits metallic absorption over these wavelength ranges. By contrast,  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> is a semiconductor with a band gap of 0.14 eV and a calculated conductivity of  $3 \times 10^{-2}$  S cm<sup>-1</sup>.

The valence states for the three Ti sites in  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> were estimated using the link between the valence state and the bond length.<sup>21</sup> The calculated valence states for Ti(1), Ti(2), and

Fig. 6 (a)  $\chi$  vs. T at 0.5 T for flake-form  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (red) and single-crystal  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> (dashed black). (b) UV-vis and IR absorption spectra for flake-form  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (red) and single-crystal  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> (dashed black). (c) Band structures calculated by VASP for (i)  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and (ii)  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> with electron-density maps for the Fermi level displayed below. Reproduced from ref. 15, copyright 2010 Springer Nature.

Ti(3) are +3.37, +3.20, and +3.53, respectively. These values are close to that of  $Ti^{(10/3)+}$ , suggesting that the charge is delocalized over the structure. This further supports that  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> is a metallic conductor. By contrast, the valence states of  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> suggest that it has a charge-localized system of  $Ti^{3+}-Ti^{(11/3)+} Ti^{(10/3)+}$  as the valence states of Ti(1), Ti(2), and Ti(3) in  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> are +3.00, +3.79, and +3.32, respectively.

First-principles calculations for  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> indicate that the bands residing close to the Fermi level are the  $t_{2g}$  orbitals from the Ti ion octahedral 3d orbitals. These are split by coupling with adjacent Ti ions. The  $d_{xy}$  orbital on Ti(2) forms slipped  $\pi$ stacking (akin to a zig-zag chain) with the  $d_{xy}$  orbital on Ti(3), which is located at the Fermi level (Fig. 6(c), left), making  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> a metallic conductor. In semi-conducting  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>, the valence band at  $-0.60$  eV consists of a bipolaron of Ti(3)–Ti(3) formed by  $\sigma$ -bonding with the d<sub>xy</sub> orbitals on Ti(3). The conduction band at +0.71 eV mainly consists of a vacant  $d_{xz}$  orbital on Ti(2) (Fig. 6(c), right).

# 3. Pressure-induced phase transition and heat-storage properties of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>

### Material and morphology

The heat-storage properties and the pressure-induced phase transition were investigated using  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> samples synthesized using rutile-TiO<sub>2</sub> particles as the starting material.<sup>16</sup> Rutile-TiO<sub>2</sub> has a particle size of ca. 500 nm, which is much larger than

Fig. 7 (a) SEM images of (i) rutile-TiO<sub>2</sub> and (ii) stripe-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>. (b) TEM image of stripe-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> showing 200 nm  $\times$  30 nm stripe-type crystal domains. Reproduced from ref. 16, copyright 2015 Springer Nature.

anatase-TiO<sub>2</sub> (Fig. 7, upper left). The obtained sample shows a coral-like morphology composed of rectangular-shaped nanorods measuring 200 nm  $\times$  30 nm, which we refer to as stripetype  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>.

#### Pressure-induced phase transition

The pressure  $(P)$  dependence of the crystal structure of stripetype  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> was measured by PXRD. Fig. 8(a) shows the PXRD pattern of the sample at 300 K under atmospheric pressure

Fig. 8 (a) PXRD pattern of stripe-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> at ambient pressure. (b) PXRD of  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> after applying 510 MPa pressure. (c) Pressure dependence of the phase fractions of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. (d) Temperature dependence of the phase fractions of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. Reproduced from ref. 16, copyright 2015 Springer Nature.

 $(P = 0.1 \text{ MPa})$ . Rietveld analysis indicated that the sample is 80%  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and 20%  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. By applying *P* = 510 MPa, the PXRD pattern changes to that of  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> (Fig. 8(b)). Fig. 8(c) shows the pressure dependence of the phase fractions of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. The pressure where the fraction of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> becomes 50%  $(P_{1/2})$  is  $\sim 60$  MPa. Upon further heating, the pressure-formed  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> returns to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> at 470 K (Fig. 8(d)).

#### Accumulated heat energy and pressure-released energy

Differential scanning calorimetry (DSC) was performed for a detailed examination of the heat-storage process. The transition enthalpy  $(\Delta H)$  for the first-order phase transition of  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti $_3$ O $_5$  is 230  $\pm$  20 kJ L $^{-1}$  (12  $\pm$  1 kJ mol $^{-1})$  (Fig. 9(a)). During the DSC measurement as the temperature decreased, a peak did not appear, indicating that the system conserves the accumulated heat energy of the phase transition from  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>.

To measure the amount of energy released, pressure was applied to the sample to induce a phase transition of stripe-type λ-Ti<sub>3</sub>O<sub>5</sub> to β-Ti<sub>3</sub>O<sub>5</sub>. The released heat energy is 240  $\pm$  40 kJ L $^{-1},$ which is almost the same as the heat accumulated energy (Fig. 9(b)). The DSC curves show that this material conserves the heat energy of the first phase transition of  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>. However, this stored energy is released when a low pressure is applied to induce the reverse phase transition of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>.

#### Mechanism

First-principles phonon-mode calculations were conducted for a deeper understanding of the pressure-induced phase transition. Fig. 10(a) shows the calculated phonon density of states (phonon DOS) for  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. During the pressureinduced phase transition of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>, the coordination geometry of Ti(3) changes. The Ti(3)–O(4) bond forms as the Ti(3)–O(5) bond breaks. The significant phonon modes of  $\lambda$ -Ti $_{3} \mathrm{O}_{5}$  to this transition appear at 248.6  $\mathrm{cm}^{-1}$ , 318.5  $\mathrm{cm}^{-1}$ , and 445.8 cm<sup>-1</sup>. In the B<sub>u</sub> phonon mode at 445.8 cm<sup>-1</sup>, Ti(3) vibrates away from  $O(5)$  and towards  $O(4)$  (Fig. 10(b), upper). During the reverse phase transition (thermally induced), where the Ti(3)–O(4) bond is broken and the Ti(3)–O(5) bond is reformed, the significant phonon modes are  $226.7 \text{ cm}^{-1}$  and

Fig. 9 DSC measurements showing (a) the heat-induced transition of  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and (b) the pressure-induced phase transition of stripetype  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. Reproduced from ref. 16, copyright 2015 Springer **Nature** 

Fig. 10 (a) Phonon DOS for stripe-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (upper) and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> (lower). (b) Visualizations of the B<sub>u</sub> phonon mode for stripe-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (upper) and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> (lower). Reproduced from ref. 16, copyright 2015 Springer Nature.

339.3  $\text{cm}^{-1}$ . In the B<sub>u</sub> phonon mode at 226.7  $\text{cm}^{-1}$ , Ti(3) now vibrates away from O(4) towards O(5) (Fig. 10(b), lower).

The Slichter and Drickamer mean field model<sup>22</sup> was deployed to elucidate the thermodynamics of the pressureinduced phase transition from  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. In this model, G is defined by the transition enthalpy  $(\Delta H)$ , the transition entropy  $(\Delta S)$ , and an interaction parameter between the  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> phases. The change in Gibbs free energy (G) dictates the generation of stripe-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> vs.  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>, and this change is thought to occur at the surface/ interfacial energy of the nanoscale domain. Fig. 11(a) shows the G vs.  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> fraction (x) curves from this calculation. Under atmospheric pressure ( $P = 0.1$  MPa), the sample is stable as  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> after it is formed at higher temperatures due to the energy barrier for the transition between  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. When external pressure is applied, the  $G$  vs.  $x$  curves are affected. Because no energy barrier is present below 400 K for  $P = 60$  MPa, there is a pressure-induced phase transformation from  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. Fig. 11(b) plots the x vs. temperature curves for  $P = 0.1$  MPa and  $P = 60$  MPa, and Fig. 11(c) shows the x vs. pressure curve at 300 K, which represents the threshold of this pressure-induced transition.

In the SD model, this pressure-induced phase transition originates from the P $\Delta V$  term of the enthalpy change ( $\Delta H = \Delta U +$  $P\Delta V$ ). From the phonon-mode calculations, the pressureinduced change of P $\Delta V$  at 60 MPa is 0.19 kJ mol<sup>-1</sup>, which is two orders of magnitude larger than the change in internal energy ( $\Delta U$ ) of 1  $\times$  10<sup>-3</sup> kJ mol<sup>-1</sup>. The effect on  $\Delta S$  is also negligible and does not significantly contribute to the phase transition.

Fig. 11 (a) Gibbs free energy (G) vs. fraction of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (x) calculated by the Slichter–Drickamer mean-field model at (i) 0.1 MPa and (ii) 60 MPa external pressure. Blue and red circles denote  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>, respectively. (b) x vs. T curves at 0.1 MPa (blue) and 60 MPa (red) external pressures. (c) x vs. pressure curve at 300 K. Reproduced from ref. 16, copyright 2015 Springer Nature.

In developing novel heat-storage materials, structural phase transition materials have potential as heat-storage materials. In addition to the sufficient magnitude of transition enthalpy, an important criterion for a heat-storage material is to possess a thermal hysteresis in the phase transition. The larger the hysteresis, the wider the possible temperature range is for heat-storage. In the case of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>, the thermal hysteresis is so wide that this phase is maintained through all temperatures below the heat-storage temperature.<sup>15,16</sup> This is the unique characteristic of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> realizing the "long-term" heatstorage ceramic that does not release the accumulated heat unless stimulated by pressure.  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and its metalsubstituted series are the only ''long-term'' heat-storage materials up to date.

### 4. Tuning the heat-storage properties of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>

### Controlling the necessary pressure for heat release

Vehicles (e.g., cars, trucks, and buses) use heat energy from combusting fuel in an engine to gain power. The realization of technologies that can store and reuse waste heat while driving would drastically improve fuel consumption. For such applications, the necessary pressure for heat release must be low to compactly equip the heat-release system in an automobile. We investigated the effect of sintering conditions during the synthesis on the necessary pressure for heat release.<sup>23</sup>

Fig. 12 TEM image of block-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (left) with an enlarged image showing clear lattice fringes (right). Inset shows the FFT image (upper) and the corresponding lattices (lower). Reproduced from ref. 23, copyright 2019 Springer Nature.

The sample was prepared by 1300  $\degree$ C sintering of rutile-type TiO2 under a hydrogen gas flow. Rietveld analysis of the PXRD pattern determined that  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> has a monoclinic structure with a  $C2/m$  space group. The sample is comprised of blockshaped crystals (Fig. 12). The crystal size is in the submicrometer range, which is notably larger than the previously reported samples (stripe-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>). This material is called block-type lambda-trititanium-pentoxide (block-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>), which reflects the primary particle morphology.

PXRD patterns were measured at different applied external pressures to investigate the pressure effect on block-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (Fig. 13(a) and (b)). As P increases, the phase fraction of  $\lambda$ - $Ti<sub>3</sub>O<sub>5</sub>$  decreases, whereas that of  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> increases until 30 MPa. Above 30 MPa, the phase fractions remain constant. The  $P_{1/2}$  value is 7 MPa.

Fig. 13 (a) Pressure-dependent PXRD patterns from 0.1 to 60 MPa external pressures. (b) Phase fraction vs. pressure curves of block type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (blue) and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> (red). (c) Thermographic images of block-type  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> after applying external pressure at  $t = 0$ . Reproduced from ref. 23, copyright 2019 Springer Nature.

Thermography was employed to visually measure the temperature change during a pressure-induced phase transition induced by striking the sample with a hammer. The initial thermal image is blue, and the starting temperature is  $26.8 \degree C$ . After striking the sample, the thermal image changes to white, and then progressively turns red, orange, yellow, green, and finally returns to blue (Fig.  $13(c)$ ). The maximum temperature of the white area is 85.5  $\degree$ C, which is reached less than 67 ms after applying pressure. These results demonstrate that the heat energy is released immediately upon applying pressure and the temperature exponentially decreases over time with a decay time of 1.7 s. Materials for use in vehicles should have transition pressures below 10 MPa. Hence, this current heat-storage ceramic has potential for applications in automobile components near engines or mufflers, as the heat-storage ceramic can be employed to rewarm cooled internal systems when the vehicle is restarted. Additionally, changing the morphology can control the threshold pressure.

#### Controlling the heat-storage temperature

Another important property is the heat-storage temperature.  $\lambda$ - $Ti<sub>3</sub>O<sub>5</sub>$  stores heat near 200 °C and undergoes a phase transition from  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>. If the heat-storage temperature can be controlled and lowered, the potential for development as heatstorage materials will greatly expand. Thus, the effect of replacing titanium ions with other metal ions has been examined.

The synthesis of magnesium-substituted  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> was first reported by our group in  $2017<sup>24</sup>$  Subsequently, in 2019, Wang et al. discovered that with Mg-substitution, the phase-transition temperature of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\alpha$ -Ti<sub>3</sub>O<sub>5</sub> to is decreased.<sup>25</sup> We then investigated the effect on the pressure-induced phase transition of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> in 2022.<sup>26</sup>

Mg-substituted  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> ( $\lambda$ -Mg<sub>x</sub>Ti<sub>3-x</sub>O<sub>5</sub>) was synthesized using the following procedure (Fig. 14(a)). First, an aqueous ammonia solution was added to a mixed dispersion of rutile  $TiO<sub>2</sub>$  particles in aqueous magnesium acetate, forming the Mg ion-covered  $TiO<sub>2</sub>$  precursor. This precursor was sintered at 1300 °C under a hydrogen gas flow to give  $\lambda$ -Mg<sub>x</sub>Ti<sub>3-x</sub>O<sub>5</sub> (x = 0.015, 0.022, 0.043, and 0.053). SEM images showed that the samples have a coral-like shape. Increasing the Mg substitution gradually reduces the diameter of the coral-like structure (Fig. 14(b)). The diameter at  $x = 0.053$  is about half that at  $x = 0.015$ .

The heat-storage properties were evaluated by DSC measurements. The DSC curves contain endothermic peaks at heatstorage temperatures of 178 °C ( $x = 0.015$ ), 160 °C ( $x = 0.022$ ), 108 °C ( $x = 0.043$ ), and 80 °C ( $x = 0.053$ ) (Fig. 14(c)). The transition enthalpy values are 227 kJ  $L^{-1}$  (x = 0.015), 223 kJ  $L^{-1}$  (x = 0.022), 215 kJ  $L^{-1}$  (x = 0.043), and 216 kJ  $L^{-1}$  $(x = 0.053)$  (Fig. 14(d)). Mg cation substitution decreases the heat-storage temperature from 198 °C (x = 0) to 80 °C (x = 0.053), while maintaining the accumulated heat energy. This reduced heat-storage temperature can be understood by the narrowing of the thermal hysteresis loop caused by the decrease of the interaction parameter within the crystal due to defects, which is

Fig. 14 (a) Synthesis procedure of Mg-substituted  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (b) SEM images of  $\lambda$ -Mg<sub>x</sub>Ti<sub>3-x</sub>O<sub>5</sub> with a coral-like morphology. (c) DSC measurements of Mgsubstituted λ-Ti<sub>3</sub>O<sub>5</sub> samples. (d) x vs. T dependence on the transition temperature. Reproduced from ref. 26, with permission from the Royal Society of Chemistry.

supported by mean-field thermodynamic simulations proposed by Slichter and Drickamer (the SD model).

Furthermore, an Sr-substituted  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> ( $\lambda$ -Sr<sub>x</sub>Ti<sub>3-x</sub>O<sub>5</sub>) was synthesized.<sup>27</sup>  $\lambda$ -Sr<sub>x</sub>Ti<sub>3-x</sub>O<sub>5</sub> shows an endothermic peak at 67 °C (340 K) during the DSC measurement, which is below the boiling temperature of water (100  $^{\circ}$ C). Sc substitution can effectively reduce the heat-storage temperature of the heatstorage ceramics. First-principles calculations suggest that the decrease of the heat-storage temperature (=  $\Delta H/\Delta S$ ) originates from the decrease in the  $\Delta H$  value caused by Sc substitution.

As summarized in Fig. 15, the present long-term heatstorage property in  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> provides insight into a new concept called heat-storage ceramics. Heat-storage ceramics can store

Fig. 15 Concept of ''heat-storage ceramics'' showing an external stimulation-induced reversible phase transfer between  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (left) and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> (right).

heat energy for a prolonged period as latent heat and release this stored energy on demand by a pressure application. Furthermore, metal substitution on  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> is an effective approach to broaden the heat-storage performance.

As a future direction for the development of long-term heatstorage materials, controlling the thermal hysteresis is the key. Any first-order phase transition material with a thermal hysteresis can be a candidate for latent heat-storage materials, and the width of the thermal hysteresis decides the active temperature range and the energy storage period. A previous study indicates that the interaction parameter, which is affected by the crystalline size, defects, etc., influences the width of the thermal hysteresis.23,26,28 Exploring the hysteresis of various first-order phase transitions could lead to the discovery of new families of long-term heat-storage materials.

### 5. Other functions: light- and currentinduced phase transitions

### Light-induced phase transition

Herein we introduce a metal–semiconductor phase transition with  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> at ambient temperature.<sup>15</sup> This was the first demonstration of a photo-rewritable phenomenon for a metal oxide. This phenomenon is possible due to the specific state of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>, which is trapped at a thermodynamic local energy minimum.

Fig. 16 Photograph showing the result of irradiating flake-form  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> with a 532 nm nanosecond laser pulse followed by a 410 nm nanosecond laser pulse.

Irradiating the flake form of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> with 532 nm nanosecond laser light (6 ns, five shots, 1.5  $\times$  10 $^{-5}$  mJ  $\mu\text{m}^{-2}$   $\text{pulse}^{-1})$  at room temperature causes the irradiated area to change from navy to brown. Further irradiating with 410 nm laser light  $(8 \times 10^{-3} \text{ mW }\mu\text{m}^{-2})$  restores the navy color at the irradiated spot (Fig. 16). The color change by alternating light irradiation with 532 nm and 410 nm light is repeatedly observed. The XRD pattern indicated that the brown area is  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. Irradiating with 532 nm light induces a phase transition from  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>, as demonstrated by the color change of navy to brown. By contrast, irradiating with 410 nm light induces the reverse transition. A similar phase-transition pattern appears when the sample is irradiated with 355 and 1064 nm nanosecond-pulsed laser light.

The SD model can explain the mechanism of the lightinduced phase transition. As explained in Section 3, an energy barrier exists between the charge-localized  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> and chargedelocalized  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> throughout the entire temperature range when an external pressure is not applied. The light-induced phase transition from  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (navy) to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> (brown) is a transition from a thermodynamically trapped metastable phase at a local energy minimum state to the true stable phase by light. Since metallic absorption allows  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to effectively absorb light over a wide range of wavelengths from ultraviolet to near-infrared, the  $\lambda$ - to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> transition appears by irradiating with 355, 532, or 1064 nm nanosecond-pulsed laser lights. The reverse photo-induced phase transition from  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> is an excitation from the valence band to the conduction band on  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>, where the excited state changes directly to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> in the pulsed laser irradiation or as a photothermal transition from  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>.

Recently, dynamic observations of the light-induced phase transition from  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> were performed using ultrafast time-resolved PXRD measurements at the Swiss X-ray Free Electron Laser facility (Swiss-FEL).<sup>29</sup> The experiments revealed that the crystal structure of the  $Ti<sub>3</sub>O<sub>5</sub>$  crystal deforms within 500

Fig. 17 (a) Debye–Scherrer ring of a sample observed using 6.6 keV photons. (b) Photograph of sample and measurement setup. (c) Lattice distortion over time. Reproduced from ref. 29, copyright 2021 Springer **Nature** 

fs after light irradiation and the phase transition is proceeded by strain waves propagating from the light-irradiated  $Ti<sub>3</sub>O<sub>5</sub>$ surface through the crystal on the order of picoseconds (Fig. 17). This propagation speed is much faster than the phase transition caused by thermal diffusion  $(ca. 100$  ns).

#### Current-induced phase transition

As another stimulus, the electric current was investigated as a trigger for the phase transition.<sup>17</sup> A pressure-formed sample of  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> was exposed to an electric current of 0.4 A mm<sup>-2</sup>, causing the brown sample to turn navy (Fig. 18(a)). The PXRD patterns prior to and following the applied electric current showed that  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> is converted into  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (Fig. 18(b)). The threshold current of the current-induced phase transition is 0.2 A mm<sup> $-2$ </sup>, according to the electrical current dependence of the transformation of pressure-formed  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> to  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> (Fig. 18(c)). This current-induced phase transition likely originates from (i) the breaking of charge ordering or (ii) the Joule heat.<sup>30–32</sup> As shown in Fig. 6,  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> has a localized charge on  $Ti^{3+}(3)$  and an empty orbital on  $Ti^{4+}(2)$ , while  $\lambda$ - $Ti_3O_5$  has a delocalized charge on Ti(2) and Ti(3). Applying an electric current to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> impels the localized charge on Ti(3) to the vacant orbital of Ti(2), resulting in charge-delocalized  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub>.

### 6. Summary and perspectives

This article details  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and a metal-substituted series called long-term heat-storage ceramics. This metal oxide can conserve the accumulated heat energy of the phase transition

Fig. 18 (a) Color change of the sample after exposure to an electric current of 0.4 A mm<sup>-2</sup>. (b) PXRD patterns before (left) and after (right) applying current. (c) Phase fraction of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> vs. electric current. Reproduced from ref. 16, copyright 2015 Springer Nature.

with  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> and release the stored energy on demand by applying external pressure. The first section provides the background that leads to the concept of long-term heat-storage ceramics. The second section explains how  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> was first discovered and its physical properties with an emphasis on the phase transition between  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. The third section introduces the pressure-induced phase transition from  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> to  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> and the heat-storage property. The fourth section details approaches to control the heat-storage property. Increasing the particle size reduces the necessary pressure for heat release to 7 MPa, while substituting Ti with Mg or Sc decreases the heat-storage temperature below 100  $\degree$ C. The fifth section illustrates two other features: a light-induced phase transition and a current-induced phase transition between  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ - $Ti<sub>3</sub>O<sub>5</sub>$ . Such a functional metal oxide with unique heat-storage properties has potential in diverse applications (Fig. 19). For example,  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> may be used in automobile components near engines and mufflers to rewarm cooled internal systems using the conserved waste heat upon restarting.<sup>33,34</sup> Additionally, this heat-storage ceramic has potential in solar power plants, which often have nitrate-based heat-storage tanks. As  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> has both sensible and long-lasting latent heat storage, it should be a convenient alternative.<sup>5,6,35</sup> Furthermore, Mg-substituted  $\lambda$ - $Ti<sub>3</sub>O<sub>5</sub>$  or Sc-substituted  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> with low heat-storage

Fig. 19 Suggested applications for heat-storage ceramic  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> in (a) internal systems of vehicles for reheating engines and (b) energy-storage tanks in solar-power systems. Reproduced from ref. 23, copyright 2019 Springer Nature.

Fig. 20 Suggested application for heat-storage ceramics, Mg- and Scsubstituted  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> for the conservation of wasted heat energy in power plants or factories. Reproduced from ref. 27, reprinted with permission from AAAS.

temperatures should be useful to reuse heat waste at power plants or factories (Fig. 20), where 70% of the generated heat energy is wasted below 100  $^{\circ}$ C.<sup>3</sup> Heat-storage materials functioning below the boiling point of water can recapture the thermal energy from cooling water in electric power plant turbines, which is vital to prevent rising sea-water temperatures. Moreover, the heat-storage temperature can easily be tuned by changing the Mg or Sc content in  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> according to the target application. Such a tunable material series will expand opportunities to use thermal energy that has not been recycled.

In addition to heat-storage applications, the present material has potential in pressure-sensitive conductivity or optical sensors because  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> is a metallic conductor while  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> is a semiconductor. Furthermore, the light-induced and currentinduced phase transitions between  $\beta$ -Ti<sub>3</sub>O<sub>5</sub> and  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> are enticing for developing advanced electronic devices. In particular, the light-induced phase transition opens possibilities for  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> as a candidate for next-generation superhigh-density optical storage media. The future memory density is expected to achieve one terabit inch<sup>-2</sup>. The vast potential of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> has attracted many researchers: various synthesis methods have been developed, $36-49$  studies of phase transition mechanism have been reported,<sup>50–66</sup> and novel functionalities are being explored.<sup>67-76</sup> Since  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> is composed of readily available elements of titanium and oxygen, it offers harmless, sustainable, and economic features, which are advantageous in industrial applications.

One of the most important tasks for the research of  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> material family would be the investigation of the strategy for increasing the amount of stored energy, the  $\Delta H$  value between  $\lambda$ -Ti<sub>3</sub>O<sub>5</sub> and  $\beta$ -Ti<sub>3</sub>O<sub>5</sub>. This task is of high interest not only for practical applications but also for basic science unveiling the details of the structural transformation during the phase transition. Such studies will involve theoretical calculations of the phase transition dynamics as well as highly precise timeresolved measurements and novel synthetic approaches, i.e., various aspects of basic research. The present material holds numerous directions for future research.
