Synthesis, spectroscopic and structural properties of Sn(II) and Pb(II) triflate complexes with soft phosphine and arsine coordination†

Kelsey R. C[airn](http://orcid.org/0000-0001-5349-3468)s, **D** Rhys P. King, **D** Robert D. Bannister, William Levason **D** and Gillian Reid^{D*}

Reaction of the divalent M(OTf)₂ (M = Sn, Pb; OTf = CF₃SO₃) with soft phosphine and arsine ligands, L, where L = o -C₆H₄(ER₂)₂ (E = P, R = Me or Ph; E = As, R = Me), MeC(CH₂ER₂)₃ (E = P, R = Ph; E = As, R = Me), PhP(CH₂CH₂PPh₂)₂ or P(CH₂CH₂PPh₂)_{3,} affords complexes of stoichiometry M(L)(OTf)₂ as white powders, which have been characterised via elemental analysis, ${}^{1}H$, ${}^{19}F{}^{1}H$, ${}^{31}P{}^{1}H$) and ${}^{119}Sn$ NMR spectroscopy, with the expected ${}^{31}P-{}^{119}Sn$ and ${}^{31}P-{}^{207}Pb$ couplings clearly evident. The crystal structures of nine of these pnictine complexes are reported, in each case revealing retention of one or both OTf anions, which gives rise to a diverse range of coordination environments including monomers, as well as varying degrees of oligomerisation to form weakly associated (OTf-bridged) dimers, trimers and polymers. 19 F{¹H} NMR spectra indicate that the OTf is essentially anionic (dissociated) in solution. Anion metathesis of $[M(OTf)_2(MeC(CH_2PPh_2)_{3}]$ with Na[BAr^F] (BAr^F = B{3,5-(CF₃)₂C₆H₃)₄) yields the corresponding [M{MeC (CH_2PPh_2) ₃}][BAr^F]₂ salts, the crystal structures of all three (M = Ge, Sn, Pb) reveal pyramidal dications with discrete [BAr^F]⁻ anions providing charge balance. Density functional theory (DFT) calculations on these [M ${(\text{MeC}(\text{CH}_2\text{PPh}_2),\text{S})}^{2+}$ (M = Ge, Sn, Pb) dications using the B3LYP-D3 functional show the presence of a directional lone pair, which is a mixture of valence s and p_z character, with the valence p-orbital character decreasing down group 14. Natural bond orbital (NBO) analysis also shows that the natural charge at the metal centre increases and the charge on the P centre decreases upon going down group 14. PAPER

The metallic elements of group 14, germanium, tin and lead have extensive coordination chemistries, for germanium and tin in both the $M(u)$ and $M(w)$ oxidation states; in contrast very few lead($\rm iv$) complexes are known.¹⁻³ Germanium($\rm iv$) halides form mostly six-coordinate complexes with neutral N- and O-donor ligands^{1,2} but whilst GeF₄ complexes with phosphine and thioether ligands are well established, $2,4$ complexes with arsenic ligands have not been obtained, and $GeCl₄$ and phosphines give redox products $[R_3PCl][GeCl_3]$.⁴ There appear to be

no crystallographically confirmed complexes of GeI₄.⁴ In contrast, $tin(w)$ halides form many complexes with soft P, As, S and Se ligands; redox chemistry is rarely observed and even $SnI₄$ forms a significant range of complexes.^{1,3,5} Recent work has focussed on attempts to isolate $Sn(w)$ cations using halide abstraction reagents such as $\rm Na[B\{3,5\text{-}(CF_3)_2C_6H_3\}_4]$ $\rm \left(Na[Bar^F]\right)$ or Me₃SiO₃SCF₃ (TMSOTf).⁵ Coordination complexes of Ge(II) were little known for many years, but have received intensive study in the last twenty years.^{1,2} Complexes mostly contain halide co-ligands and often a central 3- or 4-coordinate core, with longer interactions to anions in neighbouring molecules in many (but not all) cases producing di-, oligo- or poly-meric structures.^{1–3,6} A rich chemistry of Ge(π) cations containing oxa -, aza- or thia-macrocycles,⁷ and group 14 tetryliumylidenes has also emerged.⁸

Pnictine chemistry of the $M(\text{II})$ centres is less developed.³ The $[GeV_2(\text{diphosphine})]$ (diphosphine = $Me_2PCH_2CH_2PMe_2$, $Et_2PCH_2CH_2PEt_2$; $X = Cl$, Br, I) are discrete four coordinate monomers with near linear GeV_2 units; the $[GeV_2]$ $C_6H_4(PMe_2)_2$] contain four-coordinate Ge weakly associated into dimers *via* X-bridges. 9 The diarsine complexes include

[†]Electronic supplementary information (ESI) available: X-ray crystallographic parameters for the structures reported (Table S1), a comparison of the bond lengths and angles determined experimentally (X-ray) with those computed by DFT (Table S2), the multinuclear NMR and IR spectra associated with each of the new compounds described (Fig. S1–S18), and the x , y and z coordinates determined from the DFT calculations. CCDC 2216189–2216200. For ESI and crystallographic data in CIF or other electronic format see DOI: [https://doi.org/](https://doi.org/10.1039/d2dt03687h) [10.1039/d2dt03687h](https://doi.org/10.1039/d2dt03687h)

 $[GeC\{\sigma-C_6H_4(AsMe_2)_2\}][GeCl_3]$ and $[GeI_2\{\sigma-C_6H_4(AsMe_2)_2\}],$ whilst the structure of $[Gex_2\{o\text{-}C_6H_4(\text{PPh}_2)_2\}]$ reveals a very asymmetrically coordinated diphosphine, possibly best described as κ¹-coordinated.⁹ Halide-free, three-coordinate pyramidal Ge(II) dications, $[Ge(PMe₃)₃][OTf]₂$, $[GeL][OTf]₂$ (L = $\text{MeC}(\text{CH}_2\text{PPh}_2)_3$, $\text{MeC}(\text{CH}_2\text{AsMe}_2)_3$, $\kappa^3\text{-P}(\text{CH}_2\text{CH}_2\text{PPh}_2)_3$), have been described very recently and the electronic structures and bonding probed by DFT calculations.¹⁰

Much less effort has been devoted to the study of $Sn(II)$ complexes compared to the detailed results available for $Sn(w)$ compounds.³ Phosphine complexes of $SnF₂$ have not been prepared, however, a series of $1:1$ complexes with $SnCl₂$ was isolated, including $\text{[SnCl}_{2}\text{[}o\text{-}C_{6}\text{H}_{4}\text{(PMe}_{2})_{2}\text{]}$ and $\text{[SnCl}_{2}\text{/}Me_{2}\text{PCH}_{2}$ CH_2PMe_2] which have a SnP_2Cl_2 core and are weakly associated into dimers via chlorine bridges.¹¹ [SnCl₂{ o -C₆H₄(PPh₂)₂}] contained a pyramidal $SnPCl₂$ core with the second phosphino group ∼3.29 Å from the tin, and like the germanium analogue is best described as containing a κ^1 -diphosphine. The product of reacting $SnCl₂$ and $Ph₂PCH₂CH₂PPh₂$ is $[(SnCl₂)₂{\mu}$ $Ph_2PCH_2CH_2PPh_2$], again with a pyramidal SnPCl₂ core linked into chains via chlorine bridges and with the diphosphine cross-linking the chains. 11 The only reported diarsine complex, $[SnCl_0-C_6H_4(AsMe_2)_2][SnCl_3]$, like the Ge(II) analogue, is cationic with a polymeric chloride bridged cation. 11 In situ $31P$ and $119Sn$ NMR data have been obtained from MeNO₂ solutions of $Sn[SbF₆]₂$ and various polydentate phosphines including $Ph_2PCH_2CH_2PPh_2$, $PhP(CH_2CH_2PPh_2)$ ₂, MeC $(\text{CH}_2\text{PPh}_2)_3$, $\{\text{Ph}_2\text{PCH}_2\text{CH}_2\text{P}(\text{Ph})\text{CH}_2\}_2$ and $\text{P}(\text{CH}_2\text{CH}_2\text{PPh}_2)_3$.^{12,13} Although the data mostly indicated three phosphine donors are bound to the tin, none were isolated and no crystallographic data are available. Paper More Comparison (ICCL)-1 and 10:143-C-14/2024 10:143-C-14/2024

The coordination chemistry of lead (n) with neutral phosphines is extremely limited.³ Recent examples of neutral diphosphine complexes are the lead(II) thiolates $[(2,6-Me₂C₆]$ $H_3S_2Pb_3\{\mu-Ph_2P(CH_2)_2PPh_2\}$ and $[(2,6-Me_2C_6H_3S)_2Pb]_3\{Me_2P$ $(CH_2)_2$ PMe₂};¹⁴ the latter contains a chain of the three lead centres linked by thiolate bridges, with the $Me₂P(CH₂)₂PMe₂$ chelating to the central Pb. The insoluble, intractable lead dihalides have meant that salts with oxo-anions, $Pb(CIO₄)₂$, Pb $(NO₃)₂$, or fluoroanions have been used.^{12,13,15} The reaction of $Pb(NO₃)₂$ with $Me₂P(CH₂)₂PMe₂$, $o-C₆H₄(PMe₂)₂$ or $Et₂P$

 $(CH_2)_2PEt_2$ (L–L) in H₂O/MeCN gave white $[Pb(L-L)(NO_3)_2]$.¹⁵ The structures of $[Pb{Me₂P(CH₂)}₂PMe₂](NO₃)₂]$ and $[Pb{o C_6H_4(PMe_2)_2\}[NO_3)_2]$ reveal chelating diphosphines and κ^2 . $NO₃$ groups occupying one hemisphere about the lead centre, with single oxygen bridges to two further nitrate groups from neighbouring molecules completing a distorted eight-coordinate geometry. $[Pb\{o-C_6H_4(PMe_2)_2\}(H_2O)(SiF_6)]\cdot H_2O$ has a chelating diphosphine, a coordinated water molecule and a coordinated $\left[\mathrm{SiF}_6\right]^{2-}$ group, with further Pb-F interactions to neighbouring molecules producing a chain polymer structure.¹⁵ Several polydentate phosphine complexes of $Pb[SbF₆]$ ₂ (expected 1:1 ratio) have also been studied by in situ ${}^{31}P(^{1}H)$ and 207 Pb NMR spectroscopy in MeNO₂ solution, although none of these complexes were isolated.^{12,13}

Here we report a systematic study of the synthesis, X-ray crystal structures and multinuclear NMR spectroscopic data on polydentate pnictine complexes of $Sn[OTf]_2$ and $Pb[OTf]_2$, and compare the results with the $Ge(n)$ analogues, and the reported complexes formed with other anions. The phosphine and arsine ligands used in this work are depicted in Scheme 1.

Experimental

Infrared spectra were recorded as Nujol mulls between CsI plates using a PerkinElmer Spectrum 100 spectrometer over the range 4000–200 cm⁻¹. ¹H, ¹⁹F{¹H}, ³¹P{¹H} and ¹¹⁹Sn NMR spectra were recorded from CD_3CN solutions using a Bruker AV400 spectrometer and referenced to Sime_4 via the residual solvent resonance (¹H), external CFCl₃ (¹⁹F), 85% $\rm{H_3PO_4}$ (³¹P) and $SnMe₄$ ($119Sn$), respectively. Duplicate microanalyses were undertaken at Medac Ltd, with the majority of measurements within ±0.4% of the theoretical value. However, in a few cases the values are slightly outside this range, reflecting the recognised inherent variability of microanalytical measurements across different facilities.¹⁶ *n*-Hexane and benzene were dried by distillation from sodium and CH_2Cl_2 and MeCN from CaH₂. All preparations were carried out under anhydrous conditions via a dry dinitrogen atmosphere and standard Schlenk and glovebox techniques. $Tin(\text{II})$ triflate and lead (II) triflate, MeC $(\text{CH}_2\text{PPh}_2)_3$, PhP(CH₂CH₂PPh₂)₂, o -C₆H₄(PPh₂)₂ and P(CH₂CH₂

 $PPh₂$ ₃ were obtained from Sigma-Aldrich. The other ligands, $o\text{-C}_6\text{H}_4(\text{PMe}_2)_2, ^{17}$ $o\text{-C}_6\text{H}_4(\text{AsMe}_2)_2, ^{18}$ and $\text{MeC}(\text{CH}_2\text{AsMe}_2)_3$ 18 were prepared by the literature methods. Although formulated as "anhydrous", the IR spectra of the $M(OTf)$ ₂ typically showed varying amounts of water, which was removed completely by drying in vacuo for a few hours before using for the synthesis of the complexes.

X-ray crystallography

Crystals suitable for single crystal X-ray analysis were grown either by layering CH₂Cl₂ solutions with *n*-hexane ([Sn(OTf)₂{ o - $C_6H_4(PMe_2)_2$ }] (1), $[Sn\{MeC(CH_2PPh_2)_3\}][BAT^F]_2$ (4), $[Sn(OTf)\{PRBr_2\}$ $[CH_2CH_2PPh_2]_3$][OTf] (7), $[Sn(OTf)_2[o-C_6H_4(PPh_2)_2]$ (8), $[Pb$ $(\mathrm{OTf})_{2}\{\mathit{o}\text{-} \mathrm{C}_6\mathrm{H}_{4}(\mathrm{ASMe}_2)_{2}\}$] $(\mathbf{10}),$ $[\mathrm{Pb}\{\mathrm{MeC}(\mathrm{CH}_2\mathrm{PPh}_2)_{3}\}][\mathrm{BAT}^{\mathrm{F}}]_{2}$ $(\mathbf{12}),$ $[\text{Ge}\{\text{MeC}(\text{CH}_2\text{PPh}_2)_3\}][\text{Bar}^{\text{F}}]_2$ (15)), or by vapour diffusion of diethyl ether into MeCN solutions $([Sn(OTf)₂$ {o-C₆H₄(AsMe₂)₂}] (2), $\left[\text{Sn}(\text{OTf})\{\text{PhP}(\text{CH}_2\text{CH}_2\text{PPh}_2)_2\}\right]$ [OTf] (5), $\left[\text{Pb}(\text{OTf})_2\right]$ ₂. $C_6H_4(PMe_2)_2$] (9), $[Pb(OTf)_2[MeC(CH_2PPh_2)_3]$ (11), $[Pb(OTf)]P$ $[CH_2CH_2PPh_2]_3$ }][OTf] (13)).

Data collections used a Rigaku AFC12 goniometer equipped with an enhanced sensitivity (HG) Saturn724+ detector mounted at the window of an FR-E+ SuperBright molybdenum $(\lambda = 0.71073 \text{ Å})$ rotating anode generator with HF Varimax optics (100 μm focus) with the crystal held at 100 K, or a Rigaku UG2 goniometer equipped with a Rigaku hybrid pixel array detector (Hypix 6000 HE detector) mounted at the window of an FR-E+ SuperBright molybdenum ($\lambda = 0.71073$ Å) (or copper, $\lambda = 1.5406$ Å, for the three [BAr^F] salts) rotating anode generator with Arc)Sec VHF Varimax confocal mirrors (70 μm focus), with the crystal held at 100 K. Structure solution and refinement were performed using SHELX(S/L)97, SHELX2013, or SHELX-2014/7 via Olex.¹⁹ Structure solution and refinement was mostly routine, except for disorder of the OTf and BAT^F anions in some cases, details of which are provided in the relevant cif files. Details of the crystallographic parameters are given in Table 1. **Obtor Transactions**

Complex preparations

 $\left[\text{Sn}(\text{OTf})_{2}\{\text{o} \text{-} \text{C}_{6}\text{H}_{4}(\text{PMe}_{2})_{2}\}\right]$ (1). $\text{Sn}(\text{OTf})_{2}$ (125 mg, 0.30 mmol) was suspended in benzene (10 mL) before addition of o -C₆H₄(PMe₂)₂ (60 mg, 0.30 mmol), upon which the majority of solid was taken up into solution which was stirred for 2 h. The remaining particulates were removed by filtration, before the addition of $Et₂O$ (10 mL) which caused precipitation of a white solid, which was collected by filtration

and dried in vacuo. Yield: 128 mg, 69%. Required for $C_{12}H_{16}F_6O_6P_2S_2Sn$ (615.03): C, 24.43; H, 2.62. Found: C, 24.00; H, 3.04%. ¹H NMR (CD₃CN, 295 K): δ = 7.94–8.01 (m, [2H], Ar-H), 7.78-7.83 (m, [2H], Ar-H), 1.89 (d, $^2J_{\rm P-H}$ = 10.76 Hz, [12H], Me). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = –78.7 (s, OTf). ³¹P{¹H} NMR (298 K, CD₃CN): 14.5 (s, $^{1}J_{1175{\rm nP}}$ = 1796 Hz, $^{1}J_{1195{\rm nP}}$ = 1878 Hz). ¹¹⁹Sn NMR (298 K, CD₃CN): −689.7 (t, ¹J_{119SnP} = 1882 Hz).

 $\text{[Sn(OTf)_2{o-C}_6H_4(AsMe_2)_2]}$ (2). Sn(OTf)_2 (125 mg, 0.30 mmol) was suspended in CH_2Cl_2 (10 mL) before addition of o -C₆H₄(AsMe₂)₂ (86 mg, 0.30 mmol), upon which the majority of solid dissolved and the solution which was then stirred for 2 h. The remaining particulates were removed by filtration before the addition of n -hexane (10 mL) caused precipitation of a white solid, which was collected by filtration and dried in vacuo. Yield: 181 mg, 76%. Required for $C_{12}H_{16}As_2F_6O_6S_2Sn \cdot CH_2Cl_2$ (787.86) C, 19.82; H, 2.30. Found: C, 19.95; H, 2.49%. ¹H NMR (CD₃CN, 298 K): δ = 7.92-7.97 (m, [2H], Ar-H), 7.75-7.79 (m, [2H], Ar-H), 1.83 (s, [12H], Me). ¹⁹F 4H NMR (298 K, CD₃CN): δ = −79.1 (s, OTf). ¹¹⁹Sn NMR (298 K, CD₃CN): not observed; (258 K, CD₃CN): -886.5 (br s).

 $\text{[Sn(OTf)_2$/MeC(CH_2PPh_2)_3]}$ (3). Sn(OTf)_2 (83 mg, 0.20 mmol) was partially dissolved in CH_2Cl_2 (10 mL) before addition of $MeC(CH_2PPh_2)_3$ (125 mg, 0.20 mmol), upon which the majority of solid was taken up into solution. The solution was stirred for 2 h. The remaining particulates were removed by filtration, and the solution was concentrated by 50% before addition of *n*-hexane (10 mL) caused precipitation of a white solid which was collected by filtration and dried in vacuo. Yield: 177 mg, 81%. Required for $C_{43}H_{39}F_6O_6P_3S_2Sn \cdot 0.5CH_2Cl_2$ (1083.99): C, 48.20; H, 3.72. Found: C, 47.87; H, 4.26%. ¹H NMR (CD₃CN, 298 K): δ = 7.35–7.50 (m, [18H], Ar–H), 7.20–7.28 $(m, [12H], Ar-H), 3.12$ (br d, $^{2}J_{PH}$ = 12 Hz, [6H], CH₂), 2.01 (br s, [3H], Me). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = -79.2 (s, OTf). s, [3H], Me). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = −79.2 (s, OTf).
³¹P{¹H} (298 K, CD₃CN): δ = −9.4 (s, ¹J_{117SnP} = 1189 Hz, ¹J_{119SnP} = 1248 Hz). ¹¹⁹Sn NMR (298 K, CD₃CN): δ = -834.0 (q, ¹J_{119SnP} = 1242 Hz).

 $\textbf{[Sn\{MeC(CH_2PPh_2)_3\}][BAT}^{\Gamma}]_2$ (4). $\textbf{[Sn(OTf)}_2\{\text{MeC(CH}_2PPh_2)_3\}]$ (25 mg, 0.023 mmol) was suspended in CH_2Cl_2 (3 mL) before addition of Na $\left[\text{BAT}^{\text{F}}\right]$ (40 mg, 0.046 mmol) in CH₂Cl₂ (5 mL) and stirred for 30 min. The white precipitate that formed was removed by filtration before the supernatant was concentrated by 50% in vacuo and the addition of n-hexane, causing precipitation of white solid which was collected by filtration and dried in vacuo. Yield: 41 mg, 72%. Required for $C_{105}H_{63}B_2F_{48}P_3Sn$ (2469.80): C, 51.06; H, 2.57. Found: C, 51.21;

H, 2.50%. ¹H NMR (CD₃CN, 298 K): δ = 7.66–7.72 (br m, [16H], Ar–H), 7.65–7.68 (br m, [8H], Ar–H), 7.35–7.42 (br m, [18H] Ar– H) 7.22-7.27 (br m, [12H] Ar-H), 3.11 (br d, $^{2}J_{\text{PH}}$ = 12 Hz, [6H], CH₂), 1.99 (br s, [3H], Me). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = -63.4 (s, BAr^F). ³¹P{¹H} (298 K, CD₃CN): −8.9 (s, ¹J_{SnP} = 1246 Hz); (258 K, CD₃CN): –6.0 (s, $^{1}J_{1198nP}$ = 1252 Hz, $^{1}J_{1178RP}$ = 1197 Hz), ¹¹⁹Sn NMR (298 K, CD₃CN): −824.3 (q, ¹J_{SnP} = 1260 Hz); (258 K, CD₃CN): -843.7 (q, $^{1}J_{\text{SnP}}$ = 1251 Hz).

 $\left[\text{Sn}(\text{OTf})\{\text{PhP}(\text{CH}_2\text{CH}_2\text{PPh}_2)_2\}\right]$ [OTf] (5). $\text{Sn}(\text{OTf})_2$ (83 mg, 0.20 mmol) was partially dissolved in CH_2Cl_2 (10 mL) before addition of $PhP(CH_2CH_2PPh_2)_2$ (107 mg, 0.20 mmol); the mixture was stirred for 2 h. Particulates were removed by filtration, and the solution was concentrated by 50% in vacuo before addition of n-hexane (10 mL) caused precipitation of a white solid. This was collected by filtration and dried in vacuo. Yield: 141 mg, 71%. Required for $C_{36}H_{33}F_6O_6P_3S_2Sn \cdot 0.5CH_2Cl_2$ (993.86): C, 44.11; H, 3.45. Found: C, 44.58; H, 2.90%. ¹H NMR (CD₃CN, 298 K): δ = 7.78-7.84 (m, [4H], Ar-H), 7.68-7.73 (m, [2H], Ar–H), 7.50–7.64 (m, [9H], Ar–H), 7.31–7.43 (m, [6H], Ar– H), 7.16–7.23 (m, [4H], Ar–H), 3.27–3.45 (br m, [2H], CH2), 3.00–3.17 (br m, [2H], CH₂), 2.90–3.00 (br m, [2H], CH₂) 2.65–2.78 (br m, [2H], CH₂). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = −79.3 (s, OTf). ³¹P{¹H} (298 K, CD₃CN): 36.4 (t, ³J_{PP} = 21 Hz, $[P]$, $^{1}J_{1178{\text{NP}}}$ = 1266 Hz, $^{1}J_{1198{\text{NP}}}$ = 1377 Hz), 18.5 (d, $^{3}J_{\text{PP}}$ = 21 Hz, $[2P], \frac{1}{J_{117}}_{\text{SnP}} = 1460 \text{ Hz}, \frac{1}{J_{119}}_{\text{SnP}} = 1549).$ $\frac{119}{\text{Sn}} \text{ NMR}$ (298 K, CD₃CN): −834.0 (dt, ¹J_{SnP} = 1544 Hz, ¹J_{SnP} = 1386 Hz). Yield: 112 mg, 50%. Required for $C_{44}H_{42}F_6O_6P_4S_2Sn \cdot 0.5CH_2Cl_2$ (1121.99): C, 47.30; H, 3.84. Found: C, 47.39; H, 3.32%. ¹H NMR (CD₃CN, 298 K): δ = 7.38–7.45 (m, [18H], Ar–H), 7.29–7.34 $(m, [12H], Ar-H)$, 2.83–2.94 (br m, [6H], CH₂), 2.63–2.74 (br m, [6H], CH₂]. ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = -79.2 (s, OTf). $[6H]$, CH₂). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = −79.2 (s, OTf).
³¹P{¹H} (298 K, CD₃CN): 37.8 (br q ³J_{PP} = 39 Hz, [P], ¹J_{PSn} = 1426 Hz), 5.5 (br d, ${}^{3}J_{\text{PP}}$ = 39 Hz, [3P], ${}^{1}J_{\text{PSn}}$ = 711 Hz); (258 K, CD₃CN): 36.3 (br s, [P], $^{1}J_{\text{SnP}}$ = 1440 Hz), 3.8 (br s, [3P], $^{1}J_{\text{SnP}}$ = 685 Hz); (298 K, CD₂Cl₂): 35.7 (q, ${}^{3}J_{PP}$ = 35 Hz, [1P], ${}^{1}J_{SnP}$ = 1103 Hz), 7.34 (d, ${}^{3}J_{\text{PP}}$ = 35 Hz, [3P], ${}^{1}J_{\text{PSn}}$ = 864 Hz); (208 K,

CD₂Cl₂): 33.9 (br s, [P], ¹ J_{SnP} = 1123 Hz), 4.59 (br s, [3P], ¹ J_{PSn} = 894 Hz). ¹¹⁹Sn NMR (298 K, CD₃CN): −778.6 (dq, ¹J_{119SnP} = 1485 Hz, $^{1}J_{1198\text{NP}}$ = 720 Hz); (258 K, CD₂CN): -796 (dq, $^{1}J_{1198\text{NP}}$ = 732 Hz, $^{1}J_{1198\text{nP}} = 1477 \text{ Hz}$.

 $\left[\text{Sn(OTf)_{2}\{o\text{-}C_{6}\text{H}_{4}(\text{PPh}_{2})_{2}\}\right](8)$. Sn(OTf)₂ (104 mg, 0.25 mmol) was partially dissolved in CH_2Cl_2 (10 mL) before addition of $o\text{-}C_6H_4(\text{PPh}_2)_2$ (112 mg, 0.25 mmol) and then stirred for 2 h. The solution was concentrated by 50% before addition of n-hexane (10 mL) caused precipitation of a white solid which was collected by filtration and dried in vacuo. Yield: 151 mg, 70%. Required for $C_{32}H_{24}F_6O_6P_2S_2Sn$ (863.31): C, 44.52; H, 2.80. Found: C, 44.20; H, 2.77%. ¹H NMR (CD₃CN, 298 K): δ = 7.76–7.79 (br s, [2H], Ar–H), 7.50–7.57 (br m, [6H], Ar–H), 7.46 (br s, [16H], Ar–H). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = –79.2 (s, OTf). ${}^{31}P_1{}^{1}H$ } (298 K, CD₃CN): 19.8 (br s); (CD₃CN, 258 K): 22.7 $(s, \frac{1}{5}J_{\text{SnP}} = 1506 \text{ Hz}).$ 1¹⁹Sn NMR (298 K, CD₃CN): −809 (br s); $(CD_3CN, 258 K): -1150 (br t, \frac{1}{1195 \text{nP}} = 1550 Hz).$

 $[Pb(OTf)₂{o-C₆H₄(PMe₂)₂}]$ (9). $Pb(OTf)₂$ (151 mg, 0.30 mmol) was partially dissolved in CH_2Cl_2 (10 mL) before addition of o -C₆H₄(PMe₂)₂ (60 mg, 0.30 mmol), and the solution stirred for 2 h, during which the majority of solid dissolved. The solution was filtered before the addition of $Et₂O$ (10 mL) caused precipitation of a white solid which was collected by filtration and dried in vacuo. Yield: 128 mg, 58%. Required for $C_{12}H_{16}F_6O_6P_2PbS_2.0.5Et_2O$ (740.58): C, 22.71; H, 2.86. Found: C, 22.56; H, 3.28%. 1 H NMR (CD₃CN, 298 K): δ = 7.90–7.95 (m, [2H], Ar–H), 7.73–7.76 (m, [2H], Ar–H), 1.98–2.01 (br m, [12H], Me). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = -79.2 (s, OTf). ³¹P{¹H} (298 K, CD₃CN): δ = 74.9 (s, ¹J_{PbP} = 1777 Hz).

 $[Pb(OTf)_2[o-C_6H_4(AsMe_2)_2]$ (10). $Pb(OTf)_2$ (126 mg, 0.25 mmol) was suspended in benzene (10 mL) and $o\text{-}C_6H_4(AsMe_2)$ (72 mg, 0.25 mmol) and stirring for 2 h. Remaining particulates were removed by filtration before the addition of $Et₂O$ (10 mL) caused precipitation of a white solid which was filtered off and dried in vacuo. Yield: 101 mg, 51%. Required for $C_{12}H_{16}As_2F_6O_6PbS_2$ (791.41): C, 18.21; H, 2.04. Found: C, 18.40; H, 2.36%. 1 H NMR (CD₃CN, 298 K): δ = 7.83–7.87 (m, [2H], Ar–H), 7.57–7.62 (m, [2H], Ar–H), 1.78 (s, [12H], Me). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = –79.1 (s, OTf).

 $[Pb(OTf)_2\{MeC(CH_2PPh_2)_3\}]$ (11). $Pb(OTf)_2$ (101 mg, 0.20 mmol) was dissolved in $CH₃CN$ (10 mL) before the addition of $MeC(CH_2PPh_2)_3$ (125 mg, 0.20 mmol) and the reaction mixture was stirred for 2 h. Remaining particulates were removed by filtration, the solution was concentrated by 50% causing the precipitation of a white solid which was collected by filtration and dried in vacuo. Yield: 115 mg, 51%. Required for $C_{43}H_{39}F_6O_6P_3PbS_2$ (1130.01): C, 45.70; H, 3.48. Found: C, 45.64; H, 3.80%. ¹H NMR (CD₃CN, 298 K): δ = 7.33-7.40 (br m, [18H], Ar-H), 7.23-7.29 (m, [12H], Ar-H), 3.04 (br s, [6H], CH₂), 1.65 (br s, [3H], Me). ¹⁹ F ^{{1}H} NMR (298 K, CD₃CN): δ = -79.2 (s, OTf). ³¹P{¹H} (298 K, CD₃CN): δ = 11.6 (s), ¹J_{PbP} = 1150 (Hz).

 $[Pb{MeC} (CH_2PPh_2)_3][BAr^F]$ ₂ $[12]$. $[Pb(OTf)₂]$ MeC $(CH_2PPh_2)_3$ (45 mg, 0.04 mmol) was suspended in CH_2Cl_2 (5 mL) before addition of Na $[\text{BAT}^F]$ (71 mg, 0.08 mmol) in CH_2Cl_2 (5 mL) stirred for 30 min. Over this time the solution remained slightly cloudy, but any remaining solid had changed texture, suggesting formation of a product. Solids were removed by filtration before the solution was concentrated by 50%. Addition of n-hexane (10 mL) caused precipitation of a white solid which was collected by filtration and dried in vacuo. Yield: 50 mg, 49%. Required for $C_{105}H_{63}B_2F_{48}P_3Pb$ (2558.29): C, 49.30; H, 2.48. Found: C, 49.28; H, 2.01%. ¹H NMR (CD₃CN, 298 K): δ = 7.83-7.86 (br m, [16H], Ar–H), 7.67 (br s, [8H], Ar–H), 7.33–7.58 (br m, [6H], Ar–H), 3.45–3.50 (br m, [6H], CH₂), 1.96–1.99 (br m, [3H], Me).
¹⁹F{¹H} NMR (298 K, CD₃CN): δ = −63.4 (s, BAr^F). ³¹P{¹H} (298 K, CD₃CN): 15.5 (br s); (298 K, CD₃NO₂): 15.8 (s), ¹J_{PbP} = 1777 Hz.

 $[Pb(OTf)\{P(CH_2CH_2PPh_2)_3\}][OTf]$ (13). $Pb(OTf)_2$ (101 mg, 0.20 mmol) was added to MeCN (10 mL) followed by $P(CH_2CH_2PPh_2)_3$ (134 mg, 0.20 mmol), upon which the majority of solid dissolved; the mixture was stirred for 2 h. Remaining particulates were removed by filtration, and the solution was concentrated to 50% volume before the addition of *n*-hexane (10 mL), which caused precipitation of a white solid. This was collected by filtration and dried in vacuo. Yield: 89 mg, 38%. Crystals were grown from CH_2Cl_2 solution. Required for $C_{44}H_{39}F_6O_6P_4PbS_2.0.3CH_2Cl_2$ (1172.99): C, 44.94; H, 3.60. Found: C, 44.42; H, 3.96%. 1 H NMR (CD₃CN, 298 K): δ = 7.37–7.48 (m, [18H] Ar–H), 7.30–7.34 (m, [12H], Ar–H), 2.79–2.90 (br m, [6H], CH₂), 2.58–2.70 (br m, [6H], CH₂). ¹⁹F 4H NMR (298 K, CD₃CN): δ = −79.2 (s, OTf). ³¹P{¹H} (298 K, CD₃CN): δ = 77.5 (q, ¹J_{PbP} = 437 Hz, ³J_{PP} = 44 Hz, [P]), 26.1 (d, ¹I_J, -1870³I_J, -44 Hz, [3P])</sub> $J_{\rm PbP}$ = 1870, $^3J_{\rm PP}$ = 44 Hz, [3P]).

 $[Pb(OTf)_2\{MeC(CH_2AsMe_2)_3\}]$ (14). $Pb(OTf)_2$ (101 mg, 0.20 mmol) was partially dissolved in $CH₃CN$ (10 mL) before addition of $MeC(CH₂AsMe₂)₃$ (125 mg, 0.20 mmol), and the mixture then stirred for 2 h. The solution was concentrated by 50% before addition of $Et₂O$ (10 mL) caused precipitation of a white solid over 10 min of stirring and was then collected by filtration and dried in vacuo. Yield: 41 mg, 23%. Required for $C_{13}H_{27}As_3F_6O_6PbS_2$ (889.43): C, 17.55; H, 3.06. Found: C, 17.11; H, 3.09%. ¹H NMR (CD₃CN, 298 K): δ = 2.21 (s, [6H], CH₂), 1.61 (s, [18H], Me), 1.16 (s, [3H], Me). ¹⁹F{¹H} NMR (298 K, CD₃CN): δ = -79.3 (s, OTf) .

 $\begin{bmatrix} \mathsf{Ge}\{\mathsf{MeC}(\mathsf{CH}_2\mathsf{PPh}_2)_3\} \end{bmatrix} \begin{bmatrix} \mathsf{BAr}^{\text{F}} \end{bmatrix}_2 \quad \text{(15).} \quad \begin{bmatrix} \mathsf{Ge}\{\mathsf{MeC}(\mathsf{CH}_2\mathsf{PPh}_2)_3\} \end{bmatrix}$ $\mathrm{[OIf]_{2}}^{\mathrm{9}}$ $(0.050 \text{ g}, 0.05 \text{ mmol})$ was suspended in CH₂Cl₂ $(1 \text{ mL}),$ $\text{Na}[\text{BAT}^{\text{F}}]$ (0.089 g, 0.10 mmol) added, the solution was stirred for ∼10 min, forming a colourless solution with a small amount of precipitate (NaOTf). The supernatant was filtered away from the solid and layered with n -hexane (2 mL). After 24 h colourless crystals formed which were isolated by filtration and dried in vacuo. The crystals were suitable for single crystal X-ray diffraction. Yield: 0.068 mg, 56%. Required for C₁₀₅H₆₃B₂F₄₈P₃Ge (2423.59): C, 52.03; H, 2.62. Found: C, 52.26; H, 2.84%. ^1H NMR (298 K, CD₂Cl₂): δ = 7.71–7.75 (m, [16H], Ar–H), 7.55–7.57 (s, [8H], Ar) 7.38–7.43 (m, [6H], Ar–H), 7.20–7.25 (m, [24H], Ar–H), 3.02-3.07 (m, [6H], CH₂), 2.12-2.18 (q, [3H], $^{4}J_{\text{PH}} = 4.0$ Hz, Me). ¹⁹F{¹H} NMR (298 K, CD₂Cl₂): δ = -62.8 (s, BAr^F). ³¹P 4H NMR (298 K, CD₂Cl₂): δ = -4.34 (s).

DFT calculations

The electronic structures of the set of dications, [M{MeC $(CH_2PPh_2)_3$ ²⁺ (M = Ge, Sn, Pb; (4), (12), (15)), were investigated using DFT calculations using the Gaussian 16 W software package.²⁰ The density functional used was B3LYP-D3,²¹ with the basis set 6-311G(d) for H, C, P and Ge atoms²² and the lanl2dz basis set for the Sn and Pb atoms.²³ For $M = Ge$ and Sn the initial geometries were taken from their crystal structures, while for $M = Pb$ the initial geometry chosen was from the optimised structure of $M = Sn$ with the tin atom replaced for lead. Calculations for all structures converged with no imaginary frequencies. The calculated structures were found to be in good agreement with the crystallographicallyderived metrics (see Table S2†).

Results and discussion

The triflate complexes were prepared in good yield by reaction of a suspension of $M[OTf]_2$ (M = Sn, Pb) in an organic solvent with a solution of the di-, tri- or tetra-pnictine ligand in a 1 : 1 molar ratio (Scheme 2). The Bar^F salts were prepared from the triflate complexes by metathesis with $\text{Na}[\text{BAT}^{\text{F}}]$ in CH_2Cl_2 . The complexes were white powders or colourless crystals with a 1 : 1 M : pnictine ratio confirmed by microanalysis, with the solids being stable over several weeks in dry air and in daylight. In solution some slow degradation hydrolysis is observed via NMR spectroscopy after 2–3 h. The related literature (Introduction) suggests that many of the complexes are likely to be oligomeric, $3,9,11,15$ and only very limited data on the solids is provided by spectroscopy. We therefore determined the X-ray crystal structures of six of the tin and five of the lead complexes and discuss these first. The multinuclear NMR spectroscopic behaviour will then be considered to explore the solution speciation. **Obtor Transactions**

X-ray crystal structures

The structure of $\left[\text{Sn}(\text{OTf})_{2}\right]\left[o\text{-}C_{6}H_{4}(\text{PMe}_{2})_{2}\right]$ (1) shows a distorted four-coordinate tin core, which could be described as tetragonal pyramidal or as a trigonal bipyramid with a vacant equatorial vertex (Fig. 1(a)). The Sn–P distances are not significantly different from those in $\left[\text{SnCl}_2\right]_2C_6H_4(\text{PMe}_2)_2\}^{11}$ and the two coordinated triflates have O–Sn–O angles of 144.36(14)°. However, while $[\text{SnCl}_2\{\text{o-C}_6\text{H}_4(\text{PMe}_2)_2\}]^{11}$ forms a dimeric unit via chloride bridges, in the triflate complex two triflates from neighbouring molecules also coordinate weakly (Sn⋯O ∼3.0 Å) to form a trimeric assembly (Fig. 1b), well within the sum of the van der Waals radii for Sn + O (3.69 Å).²⁴ Note that we have considered M…O distances up to 0.3 Å below the sum of the van der Waals distances to be long, weak interactions.

In the Ph-substituted diphosphine analogue, $\frac{\text{Sn(OTf)}_{2}\text{O}}{2}$ $C_6H_4(PPh_2)_2$ (8), the two $d(Sn-P)$ are quite similar (2.7179) (10), 2.8186(11) Å), which contrasts with the essentially κ^1 . coordination of the diphosphine present in the reported $tin(II)$ chloride analogue, $[SnCl₂{o-C₆H₄(PPh₂)₂}],$ where $d(Sn-P)$ = 2.8293(9) and 3.285(1) \mathring{A}^{11} The $\left[\text{Sn}(\text{OTf})_2 \{ \text{o} - C_6 H_4(\text{PPh}_2)_2 \} \right]$

Scheme 2 Synthesis routes to the pnictine complexes reported in this work.

Fig. 1 (a) View of the structure of the Sn1-centred $[Sn(OTH)₂(o-C₆H₄(PMe₂)₂)]$ (1) moiety in the asymmetric unit showing the atom numbering scheme (there is a similar, but crystallographically independent Sn2-centred moiety in the asymmetric unit). H atoms are omitted for clarity. Ellipsoids are drawn at the 50% probability level. There are two slightly different molecules in the cell, only one is shown. Selected bond lengths (Å) and angles (°) for the Sn1-centred unit: Sn1–P1 = 2.6723(14), Sn1–P2 = 2.6682(15), Sn1–O1 = 2.346(4), Sn1–O4 = 2.527(4), Sn1⋯O3' = 2.967(4), Sn1⋯O8 = 3.002(4), P2–Sn1–P1 = 75.85(5), O1–Sn1–P1 = 77.890(11), O1–Sn1–P2 = 79.14(11), O1–Sn1–O4 = 144.36(14), O4–Sn1–P1 = 72.74(9), O4–Sn1–P2 = 74.50(11); (b) the weakly associated trimeric unit.

molecules in (8) form weakly associated dimers containing one κ^1 -coordinated OTf per tin centre (Sn1-O1 = 2.472(3) Å) and two bridging triflates with longer (weaker) Sn⋯OTf contacts (Fig. 2).

The core structure of the diarsine complex, $\left[\text{Sn(OTf)}_{2}\right]$ $C_6H_4(AsMe_2)_2$ (2) (Fig. 3(a)) is similar to that of its diphosphine analogue, $\left[\text{Sn}(\text{OTf})_{2}\right]\left[\text{o-C}_{6}\text{H}_{4}(\text{PMe}_{2})_{2}\right]$ (1), although, unlike the phosphorus analogue, the triflates are symmetrically bound (due to crystallographic symmetry). This complex also oligomerises via long Sn⋯OTf contacts (Fig. 3(b)).

The structure of $[\text{Sn}\{\text{MeC}(\text{CH}_2 \text{PPh}_2)_3\}][\text{BAT}^{\text{F}}]_2$ (4) (Fig. 4), as expected, shows no cation–anion interaction due to the diffuse nature of the large BAT^F anion. In this case the tin is in a P_3 trigonal pyramidal geometry, with all three Sn–P bond distances in the range $2.6194(4)$ –2.6438(4) Å, *i.e.* rather shorter than in the complexes described above with coordinated triflate. This probably reflects the lower coordination number and higher cationic charge.

The complexes $\left[\text{Sn}(\text{OTf})\right]\text{PhP}(\text{CH}_2\text{CH}_2\text{PPh}_2)_2\}\left[\text{OTf}\right]$ (5) and $\left[\text{Sn}(\text{OTf})\right]\left[\text{P}(\text{CH}_2\text{CH}_2\text{PPh}_2)\right]$][OTf] (7) involve coordination to Sn

Fig. 2 View of the OTf-bridged dimer present in $[Sn(OTf)_2(o-C_6H_4(PPh_2)_2)]$ (8) showing the atom numbering scheme. H atoms and CH₂Cl₂ solvent are omitted for clarity. Ellipsoids are drawn at the 50% probability level. Selected bond lengths (Å) and angles: Sn1–P1 = 2.7179(10), Sn1–P2 = 2.8186 (11), Sn1–O1 = 2.472(3), Sn1–O4 = 2.394(3), Sn1⋯O5 = 2.751(3), Sn1⋯O6 = 3.318(4), P1–Sn1–P2 = 69.80(3), O1–Sn1–P1 = 76.66(7), O1–Sn1–P2 = 76.94(8), O4–Sn1–P1 = 91.53(10), O4–Sn1–P2 = 85.14(8), O4–Sn1–O1 = 161.06(11).

Fig. 3 (a) View of core of [Sn(OTf)_2 {o-C₆H₄(AsMe₂)₂}] (2) showing the atom numbering scheme. H atoms are omitted for clarity. Ellipsoids are drawn at the 50% probability level. Selected bond lengths (Å) and angles (°): Sn1–As1 = 2.7585(2), Sn1–O1 = 2.4438(12), Sn1⋯ O2 = 3.0094(14), O1– Sn1–O1 = 137.76(6), O1–Sn1–As1 = 73.75(3), As1–Sn1–As1 = 76.755(8); (b) part of the polymeric chain with bridging OTf groups viewed down the b-axis.

 \ln *via* a P₃O donor set, with a further long, weak interaction to the second triflate completing a very distorted five-coordinate geometry (Fig. 5). The Sn–P bond lengths range from 2.6800 (12) –2.8412(7) Å, are longer than in the tripodal dication in [Sn ${ \mbox{Mec}(\rm CH_2PPh_2)_3 }[[\rm BAr^F]_2$ (4), discussed above and the fourth phosphine group $(-PPh_2)$ in $[Sn(OTf)](PH_2CH_2PPh_2)_3][OTf]$ (7) points away from the tin and is not involved in coordination. The $Ge(\mathbf{u})$ analogue adopts a three-coordinate pyramidal structure, with the triflate anions not coordinated.¹⁰ In both of these structures, as expected, the P–Sn–P angles involved in the five-membered chelate rings are substantially smaller than the much less constrained P1–Sn–P3 angles.

Moving now to the crystal structures determined for the $Pb(\Pi)$ complexes, the four-coordinate core geometry in [Pb] $(OTf)_{2}$ { o -C₆H₄(PMe₂)₂}] (9) (Fig. 6(a)) is very similar to that in the corresponding tin complex (above), and the coordination through bridging triflate groups (longer Pb⋯OTf contacts) from neighbouring molecules results in a zig-zag polymer chain with (effectively) six-coordination about the lead (Fig. $6(b)$) (there is a further OTf group 3.26 Å away from the Pb centre, but this distance is only 0.28 Å within the sum of the van der Waals radii for Pb + O, 3.54 \AA ²⁴ and therefore we do not consider this to be a significant interaction).

Fig. 4 View of the cation in $[Sn{MeC(CH₂PPh₂)}][BAT^F]₂ (4) showing the$ atom numbering scheme. H atoms are omitted for clarity. Ellipsoids are drawn at the 50% probability level. Selected bond lengths (Å) and angles: $Sn1-P1 = 2.6438(4)$, $Sn1-P2 = 2.6194(4)$, $Sn1-P3 = 2.6249(4)$, $P1-Sn1-P3 = 2.6438(4)$ $P2 = 82.120(13)$, $P1 - Sn1 - P3 = 80.761(14)$, $P2 - Sn1 - P3 = 80.160(14)$.

The lead(II) diarsine complex, $[Pb(OTf)_2\{o-C_6H_4(AsMe_2)_2\}]$ (10), has core $PbAs₂O₂$ coordination and also forms a chain polymer via weakly bridging OTf groups, with overall six-

coordination at $Pb(\Pi)$ and with two very similar Pb-As distances (Fig. 7).

The crystal structure of $[Pb(OTf)]P(CH_2CH_2PPh_2]_3][OTf]$ (13) is isomorphous with the tin analogue above, showing P_3O_2 coordination, with the third pendant -PPh₂ group remaining uncoordinated, and with the P1–Pb–P3 angle rather more open than those involving the constrained five-membered chelate rings (Fig. 8).

The structure of the lead triflate complex with the tripodal triphosphine, $[Pb(OTf)₂$ {MeC(CH₂PPh₂)₃}] (11), reveals a dimer with three bridging (and one ionic) triflates (Fig. 9), and therefore is better formulated as $[\{Pb\{MeC(CH_2PPh_2\}_3\}]_2(\mu-$ OTf)₃][OTf]. In contrast, the corresponding BAT^F salt, [Pb{MeC $(CH_2PPh_2)_3$][BAr^F]₂ (12), shows a discrete three-coordinate cation (Fig. 10(a)). Comparison of the $[BAr^F]$ and OTf structures shows longer Pb–P bonds in the latter, attributable to the higher coordination number. The P–Pb–P bond angles of the triflate bridged species ranged from 71.678(13)–77.348(13), significantly more acute than those seen in the Bar^F salt (77.868) (17) –80.594 (17) °).

We also prepared the lighter group 14 congener ($M = Ge$), $[\text{Ge}\{\text{MeC}(\text{CH}_2\text{PPh}_2)_3\}][\text{Bar}^{\text{F}}]_2$ (15), and determined its structure (Fig. 10(b)). The three salts, $[M\{Mec(CH_2PPh_2)_3\}][BAT^F]_{2}$ (M = Ge, Sn, Pb), are isomorphous $(P₁)$. As indicated in the Introduction, it is very unusual to find three isomorphous structures for pnictine complexes of these three elements, and as can be seen from Table 1, the M–P bond distances increase in the order $Ge < Sn < Pb$, and the P–M–P angles decrease in

Fig. 5 (a) View of the structure of $[Sn(OTf)\{PhP(CH_2CH_2Ph_2\}][OTf]$ (5) showing the atom numbering scheme. H atoms are omitted for clarity. Ellipsoids are drawn at the 50% probability level. Selected bond lengths (\hat{A}) and angles (°): Sn1–P1 = 2.6800(12), Sn1–P2 = 2.7655(12), Sn1–P3 = 2.7627(12), Sn–O1 = 2.623(4), Sn⋯O4 = 2.821(4), P1–Sn1–P2 = 74.52(4), P1–Sn1–P3 = 90.23(4), P2–Sn1–P3 = 72.35(4); (b) view of the structure of $[Sn(OTf)_{P}(CH_{2}CH_{2}PPh_{2}]_{3}]$ [OTf] (7) showing the atom numbering scheme. the same order. The increase in $d(M-P)$ down group 14 is consistent with the increase in the covalent radii.²⁵

Spectroscopic data

To probe the solution speciation, multinuclear NMR spectra $(^{1}H, {}^{19}F(^{1}H), {}^{31}P(^{1}H)$ and $^{119}Sn)$ were recorded, usually from CD_3CN or CD_3NO_2 , or, if solubility permitted, from CD_2Cl_2 solutions. The ^{1}H spectra (see Experimental and ESI†) were consistent with the coordinated pnictine, but were otherwise rather uninformative. The $^{19}{\rm F} \{^1{\rm H}\}$ data of the triflate complexes each show a sharp singlet at *ca*. −79 ppm, assigned to ionic triflate, indicating that the [OTf][−] groups are at best weakly associated or exchanging in solution. The ${}^{31}P{^1H}$ and ${}^{119}Sn$ spectra are much more informative and key data are summarised in Table 2, with representative examples shown in Fig. 11 and 12, (full data are in the Experimental section and the ESI†). Table 2 also summarises data on related $[M(\text{phosphine})][SbF_6]_2$ taken from the in situ studies by Dean and co-workers. $12,13$ In some cases three examples with different anions are known for a specific phosphine, for example $\left[\text{Sn}\right\} \text{MeC}\left[\text{CH}_2\text{PPh}_2\right]_3 \left|\text{Y}_2\right|$ with $Y^- = [BAr^F]^-$, $[SbF_6]^-$ and $[Off]^-$. The ¹¹⁹Sn chemical shifts for these are very similar, indicating the phosphine plays the dominant role. The ${}^{31}P_1{}^{1}H$ } NMR chemical shifts

Selected bond lengths (A) and angles (°): Pb1-P1 = 2.7771(8), Pb1-P2 = 2.8021(7), Pb1-P3 = 2.9185(7), Pb1–O1 = 2.7514(19), Pb⋯O4 = 2.951(2), P1–Pb1–P2 = 72.95 (2), P1–Pb1–P3 = 96.20(2), P2–Pb1–P3 = 70.72(2), O1–Pb1–P1 = 71.18 (5), O1–Pb1–P2 = 75.99(4), O1–Pb1–P3 = 146.61(4).

and the coupling constants are much more variable, possibly reflecting the different solvents in some cases, and probably some interaction of the anions or phosphine exchange. While coordination by $\left[\mathrm{SbF}_6\right]^-$ is viewed as rare, 26 examples are known in the solid state, and coordinated triflate is well known.

Also notable are the NMR data on the [Sn{P $(CH_2CH_2PPh_2)_3$ ²⁺ cation incorporating the tripodal tetrapho-

sphine, whose ${}^{31}P$ and ${}^{119}Sn$ NMR spectra are consistent with all three $PPh₂$ groups appearing to interact with the tin, suggesting tetradentate coordination on average in solution. This is in contrast to the κ^3 -phosphine coordination found in the solid state structure of $\frac{[\text{Sn}(\text{OTf})}{\text{SP}(\text{CH}_2\text{CH}_2\text{PPh}_2)_3}[\text{OTf}](7)$ described above, in which the one pendant arm remains free. Upon cooling the solution of this complex to 258 K (MeCN), the lines broaden, but do not split, probably indicating fast exchange between coordinated and free pendant $-PPh₂$ groups, which is not frozen out at the lower temperature.

The tin-arsine complexes did not exhibit 119 Sn NMR resonances at room temperature, but broad resonances appear upon cooling the solutions to 258 K, with chemical shifts somewhat more negative than the analogous phosphine complexes.

The lead phosphine species incorporating $[{\rm SbF_6}]^-$ anions previously reported by Dean et al. were generated in situ, but never isolated.^{12,13} These solutions did exhibit ²⁰⁷Pb NMR resonances, however, although the [OTf]⁻ and [BAr^F]⁻ complexes isolated in the present study show clear ^{207}Pb lead satellites in their ${}^{31}P{^1H}$ NMR spectra, which sharpen at low temperature, we were unable to observe $207Pb$ NMR resonances in a similar chemical shift range to those in the reported work, either at room temperature or upon cooling in MeCN (258 K). For the triflate complexes it seems most likely that this is a result of rapid reversible coordination of the triflate ions (consistent with coordination of OTf groups in the crystal structures of several examples described above). The ${}^{31}P_1{}^{1}H$ } NMR data above also revealed fast phosphine exchange in solutions of some of the $Sn(II)$ and $Pb(II)$ complexes, and this may explain the absence of a ^{207}Pb NMR resonance in the $[Pb{Mec(CH_2PPh_2)_3}][BAr^F]_2$ (12) complex, where the low temperature limiting spectrum may not have been reached at 258 K, which is the low temperature limit for $MeNO₂$.

DFT calculations

The electronic structures of the set of dications, [M{MeC (CH_2PPh_2) ₃ $]^{2+}$ (M = Ge, Sn, Pb), were investigated using DFT calculations as described in the Experimental section.

For the minimum energy structures located, in all cases the HOMO orbital is associated with a valence s–p hybrid orbital

on the metal centre, along with ligand-centred lobes. HOMO−1 and HOMO−2 are associated with bonding interactions between the valence p orbitals on the ligand with p_x/p_y type orbitals on the group 14 centre and are approximately degenerate in energy (together with ligand-centred lobes); the HOMO orbitals are shown in Fig. 13 below. The degenerate LUMO and LUMO+1 orbitals are p_x/p_y orbitals on the metal

Fig. 12 The ³¹P{¹H} NMR spectrum of [Pb{MeC(CH₂PPh₂)₃})][BAr^F]₂ (12) showing the $^1\!J_{\rm 207PbP}$ coupling.

centre (Fig. 14). The metal HOMOs on $[M_{\rm N}^{\rm M}m_{\rm C}^{\rm C}(\rm CH_{2}PPh_{2})_{3}\}^{2+}$ are all directional with a mixture of valence s and p_z character, with germanium having the highest valence p-character (18.35%), followed by tin (13.75%) and lead (8.12%). This is consistent with the trend expected going down the group

The lone pair on the metal centre is anti to one of the P–C bonds on each arm of the tripodal phosphine ligand, this leads to a LP \rightarrow P–C σ^* interaction (Fig. 15). Second order perturbation theory was used to quantify the extent of this interaction (Table 3), showing that the interaction gets weaker as the group is descended, with the interaction being about half as strong in the Pb complex when compared to the Ge complex.

NBO calculations also show that the natural charge at the metal centre increases down group 14, from +0.26 for Ge to +0.76 for Sn and +0.84 for Pb. In contrast, the natural charge on the phosphorus atom decreases as the series is descended, +1.11 (M = Ge) to +0.97 (M = Sn) to +0.95 (M = Pb).

HOMO (-11.917/-11.859/-11.837 eV)

HOMO-1 (-12.063/-12.000/-11.941 eV)

HOMO-2 (-12.064/-12.020/-11.941 eV)

Conclusions

The preparation and characterisation of a series of $Sn(II)$ and $Pb(\text{II})$ triflate complexes with soft, neutral di, tri- and tetraphosphine and di- and tri-arsine ligands has been described. X-ray structural data on 12 of the complexes confirm that the structures are highly dependent upon the pnictine atom type (P vs. As) and denticity, and show that in the majority of cases, as well as coordinating to two or three P or As donor atoms, one or both of the OTf anions are also retained within the metal coordination sphere, giving rise to a diverse range of structural motifs. These include dicationic and monocationic monomers, weakly associated (OTf bridged) dimers, cyclic trimers or chain polymers, with the degree of association dependent upon the divalent group 14 ion. For example, [M $(OTf)₂{o-C₆H₄(PMe₂)₂}$, M = Ge,²⁷ Sn, Pb, shows that upon changing from $M = Ge$ to Sn to Pb, the extended structures go from dimeric to trimeric to polymeric. The triflate-bridged dimer, $[Pb{MeC}CH_2PPh_2]_3$ ₂(μ-OTf)₃][OTf], undergoes anion metathesis with Na[BAr^F], affording the pyramidal Pb(II) triphosphine dication, $[Pb{MeC} (CH_2PPh_2)_3]^{2^+}$ as its BAr^F salt.

In solution the $^{19}F{^1H}$ NMR spectra suggest that the OTf groups are dissociated, however, the $^{31}P_1^{1}H$ } NMR spectra show the expected satellite couplings to $117/119$ Sn and 207 Pb, consistent with retention of the pnictine coordination in solution, although typically the solutions require to be cooled to reach the low temperature limiting spectra (with the exception of the tetraphosphine complexes, which are still undergoing fast exchange at 258 K). Tin-119 NMR spectra show the expected multiplet couplings to the phosphine donor groups, and the ¹¹⁹Sn NMR shifts for the arsine complexes occur to low frequency (ca. 200 ppm more negative) than the corresponding phosphine species.

DFT calculations on the $[M\{Mec(CH_2PPh_2\}]\gamma^{2+}$ homologues show the presence of directional HOMO in each dication, which is a mixture of valence s and p_z character, with the valence p-orbital character decreasing on going down group 14. NBO analysis also shows that the natural charge at the metal centre increases and the charge on the P centre decreases on going down group 14.
