The effect of MnCO_3 on the gain coefficient for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions and near-infrared emission bandwidth flatness of $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ co-doped barium zinc silicate glasses†

 Ho Kim Dan,^{a,b} Nguyen Dinh Trung,^{c,d} Nguyen Minh Tam,^e L. T. Ha,^{b,*f} Nguyen Le Thai,^g Tran Dang Thanh,^h Dacheng Zhouⁱ and Jianbei Qiuⁱ

The roles of Mn^{2+} ions in the MnCO_3 compound, leading to the formation of an $\text{Mn}^{2+}-\text{Yb}^{3+}$ dimer and affecting the gain coefficient for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions and near-infrared (NIR) emission bandwidth flatness of $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ co-doped in $\text{SiO}_2-\text{ZnO}-\text{BaO}$ (SZB) barium zinc silicate glasses, were investigated in this work. The composition of all elements from the original raw materials that exist in the host glasses was determined using energy-dispersive X-ray spectroscopy (EDS). Under the excitation of a 980 nm laser diode (LD), the NIR emission of $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped SZB glasses produced a bandwidth of about 430 nm covering the O, E, and C bands. The effects of Mn^{2+} ions and the $\text{Mn}^{2+}-\text{Yb}^{3+}$ dimer on the gain coefficient for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions and bandwidth flatness of NIR emission of $\text{Er}^{3+}/\text{Tm}^{3+}$ -co-doped and $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped SZB glasses were also assigned. The optimal molar concentration of Mn^{2+} ions was determined such that the NIR bandwidth flatness of $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped SZB glasses was the flattest. In addition, the role of Mn^{2+} ions in reducing the gain coefficient for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions was also calculated and discussed.

1. Introduction

The near-infrared (NIR) emission spectra of rare earth ions (REIs), such as Pr^{3+} , Er^{3+} , Tm^{3+} , and Ho^{3+} ions, in the wavelength range from ~ 1200 to 2000 nm with the coverage of long-band (L-band), ultra-band (U-band), and (L + U)-bands have been of interest to researchers due to their expected applications in optical amplifiers and fibre lasers.^{1–3} The NIR emission spectra of the Er^{3+} -doped peak at about 1545 nm and of the

Tm^{3+} -doped peak at about 1769 nm, corresponding to ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ (ref. 4) and ${}^3\text{F}_4 \rightarrow {}^3\text{H}_6$ transitions, respectively, have been widely investigated because of their typical applications in an erbium-doped fiber amplifier (EDFA)^{5,6} and a thulium-doped fiber amplifier (TDFA).⁷ While Er^{3+} ions can be directly excited by commercial wavelengths of both 808 nm LD and 980 nm LD,^{1,5,6,8} Tm^{3+} ions can only be directly excited by the wavelength of an 808 nm LD but not by a 980 nm LD.^{9,10} Therefore, for the NIR emission spectra of Tm^{3+} -doped and $\text{Er}^{3+}/\text{Tm}^{3+}$ -co-doped glasses using a commercial wavelength 980 nm LD for excitation, Yb^{3+} ions are often introduced as a sensitizer or for a cooperative energy transfer (CET) process through dimers/trimers such as a $\text{Yb}^{3+}-\text{Yb}^{3+}$ dimer,¹¹ $\text{Cr}^{3+}-\text{Yb}^{3+}$ dimer,¹² $\text{Mn}^{2+}-\text{Yb}^{3+}$ dimer,^{13,14} or $\text{Mn}^{2+}-\text{Mn}^{2+}-\text{Yb}^{3+}$ trimer^{4,15} for direct excitation by the commercial wavelength of a 980 nm LD.¹⁶ Among the dimers, the $\text{Mn}^{2+}-\text{Yb}^{3+}$ dimer formed by transition metal ions Mn^{2+} and Yb^{3+} ions is commonly used for the CET process of NIR emission spectra of Tm^{3+} doped or $\text{Er}^{3+}/\text{Tm}^{3+}$ co-doped in host glasses.^{13,14,17} In addition to expanding the NIR spectral bandwidth for REIs, recent studies have also focused on investigating and finding solutions to flatten the NIR spectral bandwidth of these REIs to optimize the obtained NIR spectral bandwidth for optical applications.^{18–22} In our previous studies,^{23,24} we investigated, calculated, and reported solutions to widen the bandwidth as well as to enhance the near-infrared bandwidth flatness of Tm^{3+} -doped, Ho^{3+} -doped, $\text{Tm}^{3+}/\text{Ho}^{3+}$ -co-

doped, and Ho³⁺/Tm³⁺/Yb³⁺-co-doped glasses.^{19,23} The obtained results indicated that the NIR bandwidth flatness of Tm³⁺-doped, Ho³⁺-doped, Tm³⁺/Ho³⁺-co-doped, and Ho³⁺/Tm³⁺/Yb³⁺-co-doped glasses was significantly improved by the presence of Mn²⁺ ions and an Mn²⁺-Yb³⁺ dimer in the host glasses.^{13,14,23}

Following the positive results described above, in this work, we continue to examine and report the effects of Mn²⁺ ions and Mn²⁺-Yb³⁺ dimers on the gain coefficient for the ⁴I_{13/2} → ⁴I_{15/2} transition of Er³⁺ ions and NIR emission bandwidth flatness of Er³⁺/Tm³⁺/Yb³⁺-co-doped barium zinc silicate glasses with the aim of clarifying the roles of Mn²⁺ ions in the MnCO₃ compound in the formation of an Mn²⁺-Yb³⁺ dimer. Remarkably, we have attempted to determine not only the optimal BFN_NIR emission of Er³⁺/Tm³⁺/Yb³⁺-co-doped SZB glasses but also the optimal molar concentration of Mn²⁺ ions in the MnCO₃ compound such that the BFN_NIR emission of Er³⁺/Tm³⁺/Yb³⁺-co-doped SZB glasses is a maximum. In addition, the role of Mn²⁺ ions in the MnCO₃ compound in reducing the gain coefficient for the ⁴I_{13/2} → ⁴I_{15/2} transition of Er³⁺ ions was also examined. The obtained results are able to guide the selection of more optimal materials for EDFA and TDFA optical amplifiers.

2. Experimental details

2.1. Materials

In this experiment, the glass materials are fabricated by the conventional melting method. All the raw materials consisting of SiO₂, ZnO, BaO, TiO₂, MnCO₃, Er₂O₃, Tm₂O₃, and Yb₂O₃ used in this study are laboratory reagents with high purity (99.99%).

The abbreviations, chemical compositions, and detailed molar ratios are listed in Table 1.

2.2. Experimental methods

Approximately 12 g of the mixtures of raw materials were weighed for each glass sample using an electronic analytical balance. After being finely ground using an onyx mortar and pestle, these mixtures were compressed into a platinum crucible and were then heated in a German-manufactured Nabertherm electric furnace at 1580 °C for a continuous period of 50 minutes, under an air atmosphere.²³ In the process of fabrication of the host glass and the glass doped with rare earth elements, the raw material mixtures after fine grinding are often heated at a temperature that is equal to or greater than the glass transition temperature of the raw materials, (abbreviated T_g). This temperature T_g is related to the melting point temperature of the materials (T_m) through the expression $T_g = \frac{2}{3}T_m$.^{24,25} In the experiment in this study, the SiO₂, ZnO, TiO₂, BaO, Er₂O₃, Tm₂O₃, and Yb₂O₃ raw material mixtures have melting points greater than 1580 °C. However, we chose the material melting temperature of 1580 °C²³ at which these material mixtures are melted enough to form glasses.^{23,24} In the next step, the melted mixtures were poured into a mold and quenched on the surface of a stainless steel plate to form the raw glass. To increase the mechanical strength and remove thermal strain from the raw glass, all raw glass samples were annealed at ~500 °C for a continuous period of 12 hours.^{17,19,23,26} The glass samples used for optical measurements were cut to a size of ~10 mm × 10 mm × 2 mm. The edges and surfaces of these glass samples were then thoroughly polished.

The EDS spectrum was carried out using field emission scanning electron microscopy (FE-SEM), with a Jeol JSM-6510LV. Optical transmittance spectra of the glass within the wavelength range of 350 to 2000 nm were carried out using a Hitachi U-4100 UV/VIS/NIR spectrophotometer. NIR emission spectra of the glass within the wavelength range of 1300 to 2100 nm were measured using a Zolix SBP300 spectrophotometer with an InGaAs detector under excitation by a 980 nm LD. Optical transmittance and NIR emission spectra measurements as well as EDS analysis of the glass samples were performed at ambient temperature.^{17,19}

3. Results and discussion

3.1. EDS analysis

To determine whether the elements in the original raw material still exist in the glass materials after fabrication, we conducted an EDS analysis for the SZB-0.5Er1Tm2Yb2Mn glass sample, and the analyzed results within the energy range from 0 to 10 keV are plotted in Fig. 1. The energy levels of each element are listed in detail in Table 2. The obtained results of the EDS spectrum analysis of the SZB-0.5Er1Tm2Yb2Mn glass sample confirmed that the C, Ti, O, Ba, Zn, Si, Mn, Tm, Er, and Yb elements were still present in the SiO₂-ZnO-BaO-TiO₂-Er₂O₃-Tm₂O₃-MnCO₃-Yb₂O₃ glass matrix.^{27,28} It should be noted that

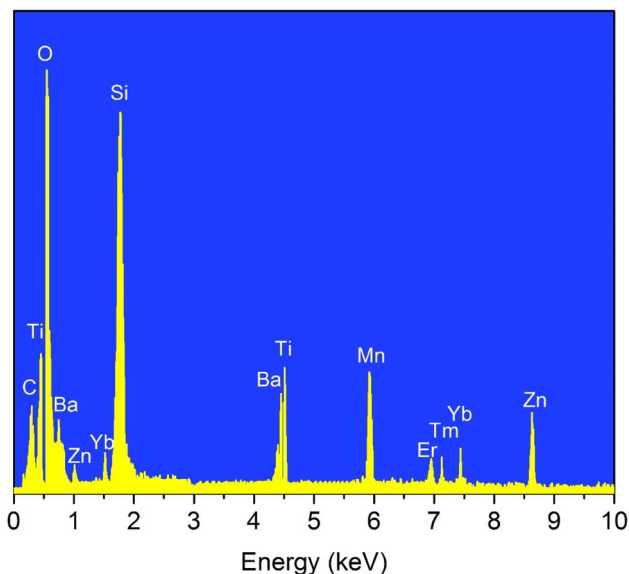

Fig. 1 EDS spectral analysis of the SZB-0.5Er1Tm2Yb2Mn glass sample.

Table 2 Details of the energy levels of the elements in the EDS spectral analysis

Energy	Element									
	C	Ti	O	Ba	Zn	Si	Mn	Er	Tm	Yb
L_{α} (keV)	0.278	0.452	0.526	0.971	1.012	1.741	0.638	1.405	7.179	1.521
K_{α} (keV)		4.509		4.466	8.629		5.895	6.946		7.415

the Mn element has many different valence states, including +2, +3, +4, +5, +6, and +7 valences. When the MnCO₃ compound is introduced into the host glasses, the Mn element exists almost exclusively in the Mn 2p1 and Mn 2p3 valence states and this was investigated through XPS analysis and reported in a previous study.¹⁷ Following the results achieved on the behavior of the MnCO₃ compound doped into barium zinc silicate glasses, the goal of this work is mainly to focus on investigating the role of Mn²⁺ ions in the MnCO₃ compound for combining to form an Mn²⁺-Yb³⁺ dimer and transferring energy to Er³⁺ and Tm³⁺ ions to enhance the NIR emission intensity of Er³⁺/Tm³⁺/Yb³⁺-co-doped barium zinc silicate glasses under 980 nm LD excitation.

3.2. Optical transmittance spectra

In Fig. 2(A), optical transmittance spectra of the SZB-0.5Er, SZB-0.5Er2Yb2Mn, SZB-1Tm, and SZB-1Tm2Yb2Mn glass samples are shown in curves (a), (b), (c) and (d), respectively. Curve (a) shows the optical transmittance spectra of the Er³⁺-doped sample in which seven optical transmittance bands can be observed corresponding to the ⁴I_{15/2} → ⁴G_{11/2}, ⁴F_{7/2}, ²H_{11/2}, ⁴S_{3/2}, ⁴F_{9/2}, ⁴I_{11/2} and ⁴I_{13/2} transitions of Er³⁺ ions.^{29,30} Curve (b) shows the optical transmittance spectrum of the Er³⁺/Yb³⁺/Mn²⁺-co-doped sample in which nine optical transmittance bands can be observed, among which, one corresponds to the ⁶A_{1g} → ⁴T_{1g} transition of Mn²⁺ ions,^{13,14,17} one corresponds to the ²F_{7/2} → ²F_{5/2} transition of Yb³⁺ ions,^{27,28} and the remaining seven correspond to the ⁴I_{15/2} → ⁴G_{11/2}, ⁴F_{7/2}, ²H_{11/2}, ⁴S_{3/2}, ⁴F_{9/2}, ⁴I_{11/2} and ⁴I_{13/2} transitions of Er³⁺ ions.^{30,31} Curve (c) shows the optical transmittance spectra of the Tm³⁺-doped in SZB-1Tm glass sample in which five optical transmittance bands can be observed corresponding to the ³H₆ → ¹G₄, ³F_{2,3}, ³H₄, ³H₅, and ³F₄ transitions of Tm³⁺ ions. Curve (d) shows the optical transmittance spectra of the Tm³⁺/Yb³⁺/Mn²⁺ co-doped in SZB-1Tm2Yb2Mn glass sample in which seven optical transmittance bands can be observed, among which, one corresponds to the ⁶A_{1g} → ⁴T_{1g} transition of Mn²⁺ ions,^{13,14,17} one corresponds to the ²F_{7/2} → ²F_{5/2} transition of Yb³⁺ ions,^{27,28,31} and the remaining five optical transmittance bands correspond to the ³H₆ → ¹G₄, ³F_{2,3}, ³H₄, ³H₅, and ³F₄ transitions of Tm³⁺ ions.^{27,28}

To more clearly observe the optical transmittance spectra of Er³⁺, Mn²⁺, and Yb³⁺ ions, we measured and further analyzed the optical transmittance spectra of the SZB-2Mn2Yb, SZB-0.5Er1Tm2Yb, and SZB-0.5Er1Tm2Yb2Mn glass samples. The analyzed results of these optical transmittance spectra are plotted in Fig. 2(B). The obtained results displayed in curve (c)

Fig. 2 (A) Optical transmittance spectra of the SZB-0.5Er, SZB-0.5Er2Yb2Mn, SZB-1Tm, and SZB-1Tm2Yb2Mn glass samples. (B) Optical transmittance spectra of the SZB-2Mn2Yb, SZB-0.5Er1Tm2Yb, and SZB-0.5Er1Tm2Yb2Mn glass samples.

of Fig. 2(B) indicate that we can also observe all nine optical transmittance bands corresponding to ${}^6A_{1g} \rightarrow {}^4T_{1g}$ of Mn^{2+} ions, ${}^2F_{7/2} \rightarrow {}^2F_{5/2}$ of Yb^{3+} ions, 4,11,13,14,17 and the ${}^4I_{15/2} \rightarrow {}^4G_{11/2}$, ${}^4F_{7/2}$, ${}^2H_{11/2}$, ${}^4S_{3/2}$, ${}^4F_{9/2}$, ${}^4I_{11/2}$, ${}^4I_{13/2}$ transitions of Er^{3+} ions,^{4,30,31} similar to the analysis above. Interestingly, the analyzed results reveal that the transmittance spectrum of the SZB-0.5Er1Tm2Yb2Mn glass samples containing Mn^{2+}

components in the wavelength region of ~ 380 – 900 nm was decreased whereas the optical transmittance spectrum in the wavelength region of ~ 900 – 2000 nm was increased compared to SZB-0.5Er1Tm2Yb glass samples without Mn^{2+} components. Also from the results displayed in Fig. 2(B), it can be seen that the optical transmittance spectrum of the SZB-2Mn2Yb glass sample within the wavelength range ~ 1000 – 2000 nm is higher than that of the SZB-0.5Er1Tm2Yb or SZB0.5Er1Tm2Yb2Mn glass samples. For the SZB-0.5Er1Tm2Yb and SZB0.5Er1Tm2Yb2Mn glass samples, in addition to the Mn^{2+} and Yb^{3+} components, there are also Er^{3+} and Tm^{3+} components with absorption peaks at about 1230 nm and 1542 nm in the wavelength range ~ 1000 to 2000 nm, corresponding to the ${}^3H_6 \rightarrow {}^3H_5$ transition of Tm^{3+} ions and the ${}^4I_{15/2} \rightarrow {}^4I_{13/2}$ transition of Er^{3+} ions, respectively. Part of the excitation energy is thus absorbed in the wavelength region from ~ 1000 to 2000 nm, which does not occur for the SZB-2Mn2Yb glass sample. This is the reason why the transmittance spectrum of the SZB-2Mn2Yb sample is higher than those of the other glass samples.

3.3. NIR emission spectra

NIR emission spectra of the SZB-0.5Er2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass samples under 980 nm LD excitation are plotted in Fig. 3. For the SZB-0.5Er2Yb glass sample, the NIR emission of Er^{3+}/Yb^{3+} -co-doped peaks at ~ 1542 nm corresponds to the ${}^4I_{13/2} \rightarrow {}^4I_{15/2}$ transition of Er^{3+} . With the increased concentrations of the $MnCO_3$ compound from 2 up to 4 mol%, the NIR emission intensity of the Er^{3+}/Yb^{3+} -co-doped peaks at ~ 1542 nm was significantly increased. Moreover, the NIR emission peak of Er^{3+} tends to split and shift the peaks by $\Delta\lambda = 1553 - 1542$ nm = 11 nm. The main reason for the increase in NIR emission intensity of Er^{3+}/Yb^{3+} -co-doped peaks at ~ 1542 nm can be attributed to the combination between Yb^{3+} and Mn^{2+} ions in the $MnCO_3$ compound leading to the formation of $Mn^{2+}-Yb^{3+}$ dimers^{13,32} contributing to the energy transfer (ET) to the ${}^4I_{13/2} \rightarrow {}^4I_{15/2}$ transition of Er^{3+} ions.^{13,23} The

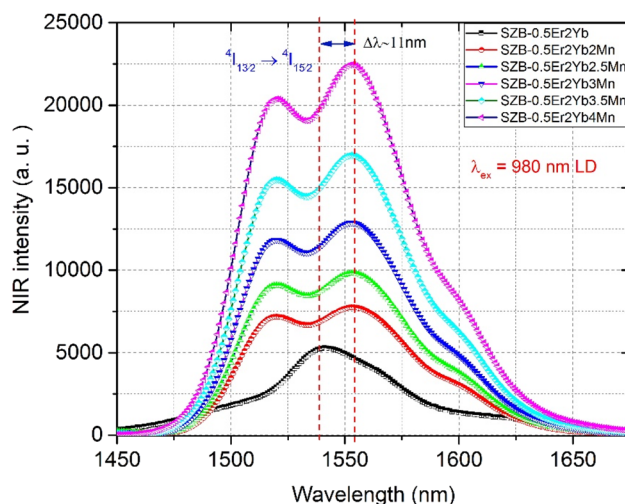

Fig. 3 NIR emission spectra of the SZB-0.5Er2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass samples.

formation of an $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimer can be interpreted with the result shown in Fig. 3, where the Er^{3+} and Yb^{3+} concentrations are unchanged when the concentration of the MnCO_3 compound increases from 2 up to 4 mol%, and the NIR emission intensity of the $\text{Er}^{3+}/\text{Yb}^{3+}$ -co-doped peaks at ~ 1542 nm under the excitation of 980 nm LD was significantly increased. However, the Mn^{2+} ions cannot receive the direct excitation of the 980 nm LD, proving that Mn^{2+} ions combine with the Yb^{3+} ions to form an $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimer,^{13,23} and therefore, the $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimers receive the excitation of the 980 nm LD and transfer energy from the $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimer to the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions.^{13,23} The addition of MnCO_3 compound into the host glass efficiently promotes not only the formation of the $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimer but also contributes to breaking of the O-Zn, Si-O, Si-O-Si, Zn-O-Zn, and Si-O-Zn bonds,³³ subsequently creating new non-bridging oxygens (NBOs), like Mn-O, Mn-Si, Si-O-Mn, Mn-O-Mn, and Mn-O-Zn bonds.^{34,35} Therefore, we believe that the presence of Mn^{2+} ions in the MnCO_3 compound contributed to shifting the NIR emission peak at the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions.

We also investigated the effects of Mn^{2+} on the NIR emission bandwidth flatness (NIR_EBF) parameter of $\text{Er}^{3+}/\text{Yb}^{3+}$ co-doped in SZB glasses. The NIR_EBF parameter of $\text{Er}^{3+}/\text{Yb}^{3+}$ co-doped in SZB glasses can be calculated based on the NIR emission spectra of $\text{Er}^{3+}/\text{Yb}^{3+}$ co-doped in SZB glasses with the following formula:^{19,23}

$$\text{NIR_EBF} = \frac{\sqrt{\prod_{n=0}^{N-1} I(n)}}{\sum_{n=0}^{N-1} I(n)} = \frac{\exp\left(\frac{1}{N} \sum_{n=0}^{N-1} \ln I(n)\right)}{\frac{1}{N} \sum_{n=0}^{N-1} I(n)} \quad (1)$$

where $I(n)$ is the NIR emission intensity of $\text{Er}^{3+}/\text{Yb}^{3+}$ co-doped in SZB glasses within the analytical data range n of the NIR emission wavelength N .^{19,23} NIR_EBF takes a value from 0 to

1.^{19,23} The value of NIR_EBF is equal to 1 when all values of $I(n)$ are equal.^{19,23} The NIR_EBF calculated results of $\text{Er}^{3+}/\text{Yb}^{3+}$ co-doped in SZB glasses displayed in Fig. 4 show that with increasing concentrations of Mn^{2+} ions, the NIR_EBF of $\text{Er}^{3+}/\text{Yb}^{3+}$ co-doped in SZB glasses gradually decreased.

Similarly, the NIR emission spectra of SZB-1Tm2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass samples under excitation of 980 nm LD are plotted in Fig. 5 and indicate that the NIR emission of the $\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped sample has two peaks at about ~ 1457 and ~ 1801 nm, corresponding to the ${}^3\text{H}_4 \rightarrow {}^3\text{F}_4$ and ${}^3\text{F}_4 \rightarrow {}^3\text{H}_6$ transitions of Tm^{3+} ions.^{36,37} Along with the increase in MnCO_3 concentration from 2 up to 4 mol%, the NIR emission intensity of $\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped peaks at ~ 1457 and ~ 1801 nm was also significantly increased. This result is due to the ET processes from the $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimer to the ${}^3\text{H}_4 \rightarrow {}^3\text{F}_4$ and ${}^3\text{F}_4 \rightarrow {}^3\text{H}_6$ transitions of Tm^{3+} ions.¹⁷

Formula (1) continued to be used to calculate the NIR_EBF spectra of $\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped samples when the molar concentration of the MnCO_3 compound increases from 0 up to 4 mol% and the results of the calculation are shown in the insert to Fig. 5. These results show that the NIR_EBF spectra of the $\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped sample reached the optimal value of 0.668 when the molar concentration of the MnCO_3 compound was 2 mol%. Energy levels of Er^{3+} , Tm^{3+} , Yb^{3+} ions, the $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimer and mechanisms of the ET_I ($I = 1, 2, 3, 4,$ and 5) processes in the SZB glass system are shown in Fig. 6. Mechanisms of the ET_I ($I = 1, 2, 3, 4,$ and 5) processes between the $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimer with Er^{3+} , Tm^{3+} ions were also reported and discussed in detail in our previous studies.^{17,26} These ET_I ($I = 1, 2, 3, 4,$ and 5) processes can be described in detail in the form of the following equations:

Fig. 4 Relationship between NIR spectra flatness of the SZB-0.5Er2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass samples and molar concentration of Mn^{2+} ions.

Fig. 5 NIR emission spectra of the SZB-1Tm2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass samples.

Fig. 6 Energy levels of Er^{3+} , Tm^{3+} , Yb^{3+} , Mn^{2+} - Yb^{3+} dimer and mechanisms of ET_l ($l = 1, 2, 3, 4,$ and 5) processes in the SZB glass system.

To achieve one of the main goals of this study, we investigated the effects of Mn^{2+} ions in the MnCO_3 compound on the NIR_EBF spectra of $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped SZB glasses. We kept the molar compositions of the $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped

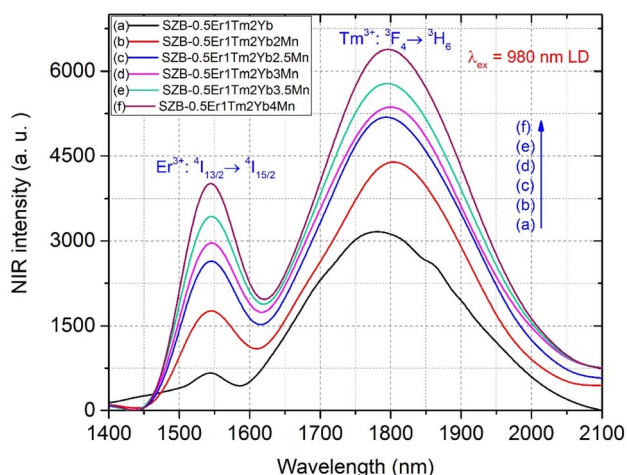

Fig. 7 NIR emission spectra of the SZB-0.5Er1Tm2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass samples.

Fig. 8 The relationship between the molar concentration of Mn^{2+} ions and NIR_EBF parameter of the SZB-0.5Er1Tm2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass samples.

sample to $0.5\text{Er}^{3+}/1\text{Tm}^{3+}/2\text{Yb}^{3+}$, and changed the molar composition of the MnCO_3 compound from 2 up to 4 mol%. As shown in Fig. 7, the NIR emission spectra of SZB-0.5Er1Tm2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass samples under excitation by a 980 nm LD reveal that when the molar concentration of the MnCO_3 compound increases from 2 up to 4 mol%, the NIR emission intensity of the $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped peaks at ~ 1553 and ~ 1801 nm also strongly increases. This result may be due to Mn^{2+} - Yb^{3+} dimers being formed during the excitation by 980 nm LD, with the energies from Mn^{2+} ions and Mn^{2+} - Yb^{3+} dimers simultaneously transferred to Er^{3+} and Tm^{3+} ions. The NIR emission spectra of $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped in the SZB-0.5Er1Tm2YbxMn ($x = 0, 2, 2.5, 3, 3.5,$ and 4 mol%) glass under 980 nm LD excitation created an NIR bandwidth of ~ 430 nm. The NIR_EBF spectra of the $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped samples were determined when the molar concentration of Mn^{2+} ions in the MnCO_3 compound increased from 2 up to 4 mol% using formula (1). The results of the calculation of the NIR_EBF value, given in Fig. 8, showed that the NIR_EBF spectra of the $\text{Er}^{3+}/\text{Tm}^{3+}/\text{Yb}^{3+}$ -co-doped sample reached the optimal value of 0.849 when the molar concentration of Mn^{2+} ions in the MnCO_3 compound was 3.5 mol%.

3.4. Cross-section and gain coefficient study

To evaluate the influence of Mn^{2+} ions in the MnCO_3 compound on the gain coefficient of Er^{3+} ($G_{\text{Er}}(\lambda)$), we first investigated and calculated the absorption cross-section $\sigma_{\text{abs}}(\lambda)$ and emission cross-section $\sigma_{\text{ems}}(\lambda)$ for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions in the SZB glasses based on McCumber's theory.^{6,38,39} The value of $\sigma_{\text{abs}}(\lambda)$ is calculated from the absorbance spectrum according to the following formula:^{6,38,39}

$$\sigma_{\text{abs}}(\lambda) = \frac{2.303}{Cd} A(\lambda), \quad (2)$$

in which $A(\lambda)$ is the absorbance spectrum; λ is the wavelength; C is the concentration of Er^{3+} ions; and d is the thickness of the

SZB glass samples, where the glass sample in this study has a thickness of $d = 2$ mm.^{6,38} The absorbance spectrum $A(\lambda)$ can be calculated from the transmittance spectrum $T(\lambda)$ according to the formula:^{40,41}

$$A(\lambda) = -\log_{10} T(\lambda) = 2 - \log_{10}(\% T(\lambda)), \quad (3)$$

where $\% T(\lambda)$ is the transmittance spectrum (measured as a percentage) determined from the experimental results in Fig. 2(A) and (B).

The value of $\sigma_{\text{ems}}(\lambda)$ is thus determined in relation to the value of $\sigma_{\text{abs}}(\lambda)$ as follows:^{6,39}

$$\sigma_{\text{ems}}(\lambda) = \sigma_{\text{abs}}(\lambda) \frac{Z_{\text{L}}}{Z_{\text{U}}} \exp\left(\frac{hc}{kT} \left(\frac{1}{\lambda_{\text{UL}}} - \frac{1}{\lambda}\right)\right), \quad (4)$$

where Z_{U} and Z_{L} are the partition functions of the upper and lower manifolds, respectively; T is the temperature; h is Planck's constant, k is Boltzmann's constant; c is the speed of light; λ is the photon wavelength; λ_{UL} the wavelength corresponding to the transition between the bottom of the excited (upper) state manifold and the bottom of the ground (lower) state manifold.^{6,35,36} The value of $\sigma_{\text{abs}}(\lambda)$ for the ${}^4\text{I}_{15/2} \rightarrow {}^4\text{I}_{13/2}$ transition and of $\sigma_{\text{ems}}(\lambda)$ for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions are determined as shown in Fig. 9. The gain coefficient $G(\lambda)$ for transitions of the REIs in the glass samples can be determined with the following formula:^{6,38,39}

$$G(\lambda) = C \cdot [P \cdot \sigma_{\text{ems}}(\lambda) - (1 - P) \cdot \sigma_{\text{abs}}(\lambda)], \quad (5)$$

in which P is the population inversion and $P = 0-1$ stands for the ratio between the number of REIs in the excited state to the total number of REIs.

Formulae (2)–(5) are used to determine the values of $\sigma_{\text{abs}}(\lambda)$, $\sigma_{\text{ems}}(\lambda)$, and $G_{\text{Er}}(\lambda)$, respectively, for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions in the SZB-0.5Er glass sample. The values of $G_{\text{Er}}(\lambda)$ were calculated and are shown in Fig. 10. We can observe that the $G_{\text{Er}}(\lambda)$ value becomes positive in the range wavelength of $\sim 1500-1600$ nm for cases where P is equal to 0.5 to 1. When P is

Fig. 9 Absorption and emission cross-sections of the SZB-0.5Er glass sample.

Fig. 10 Gain coefficient for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions in the SZB-0.5Er glass sample.

greater than 0.6, the NIR emission of the Er^{3+} -doped SZB-0.5Er glass sample exhibits a flat net gain covering the L-, U-, and (L + U)-bands.⁶ At the same time, the $G_{\text{Er}}(\lambda)$ value is found to be about 0.38, corresponding to $P = 1$. Similarly, we also used formulae (2)–(5) to determine the values of $\sigma_{\text{abs}}(\lambda)$, $\sigma_{\text{ems}}(\lambda)$, and $G_{\text{Er-Mn}}(\lambda)$, respectively, for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions in the SZB-0.5Er2Yb2Mn glass sample. The values of $\sigma_{\text{abs}}(\lambda)$ and $\sigma_{\text{ems}}(\lambda)$ of the SZB-0.5Er2Yb2Mn glass sample are shown in Fig. 11 and the values of $G_{\text{Er-Mn}}(\lambda)$ for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions in the SZB-0.5Er2Yb2Mn glass sample are shown in Fig. 12. Comparison of the results in Fig. 10 and 12 shows that with the existence of Mn^{2+} ions in the SZB-0.5Er2Yb2Mn glass sample, the value of $G_{\text{Er-Mn}}(\lambda)$ for the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+} ions was significantly reduced. The value of $G_{\text{Er-Mn}}(\lambda)$ is found to be about 0.21 corresponding to $P = 1$. These $G_{\text{Er-Mn}}(\lambda)$ and $G_{\text{Er}}(\lambda)$ calculation results showed that in the presence of Mn^{2+} ions and an $\text{Mn}^{2+}\text{-Yb}^{3+}$ dimer, the broadband NIR emission of the ${}^4\text{I}_{13/2} \rightarrow {}^4\text{I}_{15/2}$ transition of Er^{3+}
