An amorphous MgF₂ anti-reflective thin film for enhanced performance of inverted organic–inorganic perovskite solar cells†

 Wenhui Li,^a Wenhuan Cao,^a Huawei Zhou,^{ID} *^a Xianxi Zhang*^a and Kai Wang^{ID} *^b

The effective control of light plays an important role in optoelectronic devices. However, the effect of anti-reflection thin film (ARTF) in inverted perovskite solar cells (PSCs) (p-i-n) has so far remained elusive. Herein, MgF₂ ARTF with different thicknesses (approximately 100, 330, and 560 nm) were deposited on the glass side of FTO conductive glass substrates by vacuum thermal evaporation. The results of reflectance and transmittance spectroscopy show that approximately 330 nm MgF₂ ARTF can reduce reflectivity and increase transmittance on FTO conductive glass substrates. The results of SEM, XRD, and AFM show that the surface of amorphous MgF₂ ARTF possesses a lot of nanoscale pits. The effect of the MgF₂ ARTF on the performance of inverted perovskite solar cells (PSCs) (p-i-n) was investigated. The power conversion efficiencies (PCE) of inverted PSCs without and with MgF₂ ARTF are 18.20 and 21.28%, respectively. The significant improvement in PCE of the devices with MgF₂ ARTF is caused by the improvement in short-circuit current density. The stability results of the devices show that the PCE remains above 70% of the initial PCE after 300 h illumination.

1 Introduction

Photovoltaic energy has great potential for development due to the advantages of wide distribution, sustainability, safety and reliability. Photovoltaic research has attracted international attention as a result of global warming and other climate issues.^{1–3} Perovskite solar cells (PSCs) have been the subject of heated discussions in the scientific research field in the last decade, as a result of their simple technical process, and high power conversion efficiency (PCE).^{4,5}

Although the PCE of PSCs has exceeded 25%, how to further achieve a Shockley–Queisser limit of 31% is an important scientific issue.⁶ Development of tandem solar cells is a way to improve the PCE. Interface passivation can reduce recombination of photogenerated carriers. The light loss is one of the key issues for the reduction of the short-circuit current and PCE of the device due to the occurrence of refraction and reflection at the interface of the device. There are two ways to improve the PCE of the device through light control. One way is building special micro-nanostructure of the device to increase the absorption and

secondary use of photons. For example, gradient structure with active and reflective layers can improve the PCE of dye-sensitized solar cells. The anti-reflection thin film (ARTF) with a small refractive index can reduce the reflection of photons and increase their transmission. For example, SiN_x ARTF can improve PCE of crystalline silicon solar cells.^{7–9} Therefore, fabrication of ARTF is an important way to achieve high PCE.¹⁰

Magnesium fluoride (MgF₂) is used as the refractive material in the optics field because of its low refractive index and high transmittance in the visible light region.¹¹ Some researchers have applied MgF₂ ARTF to perovskite solar cell (PSCs) to reduce optical loss.^{3,12–14} However, systems research of the effect of MgF₂ ARTF (the thickness, crystallinity, chemical composition and surface morphology) on inverted PSCs have not been reported.

In this study, we prepared MgF₂ ARTF on inverted PSCs by vacuum thermal evaporation (VTE) method to improve the performance of inverted PSCs. We investigated the optical properties of MgF₂ ARTF by ellipsometry and reflectance and transmittance spectra. The morphological structure of MgF₂ ARTF was analyzed by SEM and AFM, and its optoelectronic performance was analyzed by photoelectric workstation.

2 Experiment

2.1 Preparation of MgF₂ ARTF on inverted PSCs and FTO substrate

The MgF₂ ARTF was prepared by VTE of high-purity MgF₂ (99.999%) powder using ZD-400 single-chamber ten-source

resistive vapor deposition equipment. The experimental current during deposition was 120 A. The deposition rate was 0.6 \AA s^{-1} . The inverted PSCs ($2.4 \times 2.4 \text{ cm}^2$) and FTO conductive glass substrate was selected to study the effect of MgF_2 ARTF. MgF_2 ARTF with different thicknesses were obtained by evaporating different weight (0.1, 0.5, and 1 g) of MgF_2 powder.

2.2 Preparation of inverted PSCs

The inverted PSCs (FTO/ NiO_x /Perovskite/ PC_{61}BM /BCP/Au) were fabricated using previously reported routes.¹⁵ Preparation of NiO_x films using electron beam evaporation (EBE- NiO_x): the FTO glass was ultrasonically cleaned using anhydrous ethanol and deionized water for 30 min, and was blown dry using N_2 , followed by treatment using 100 W plasma for 5 min and then transferred to an electron beam evaporation system. A oxygen flow (15 sccm) was maintained during the evaporation process to improve the quality of the NiO_x film.

The treatment of surface redox engineering (SRE) for EBE- NiO_x films: EBE- NiO_x films was treated by Ar plasma with 30 W for 2.5 min, followed by treatment of dilute nitric acid (0.015 M) (spin coating rate of 5000 rpm for 35 s).

Preparation of perovskite and electron transport layer and Au electrode: 1.14 M FAI, 1.33 M PbI_2 , 0.1 M CsI, and 0.2 M MACl were dissolved in a mixed solvent (DMF:DMSO = 4:1) and 0.06 mg mL^{-1} L- α -phosphatidylcholine and 0.33 mg mL^{-1} ionic liquid BMIMBF₄ as additives. The perovskite films were prepared on NiO_x film using above precursor solution by spinning-coating, followed by heating at 110 °C for 20 min. The 20 mg mL^{-1} PC_{61}BM solution was spin-coated at 4000 rpm for 30 s on perovskite film. The BCP saturated solution in isopropanol spin-coated on PC_{61}BM film at 4000 rpm for 40 s.

Finally, Au electrode (area of 0.09 cm^2) was deposited on the BCP film.

2.3 Characterization

The phase of MgF_2 powder and film was analyzed by XRD at 40 kV/40 mA, with a scanning speed of 10° per min, step width of 0.02° , and the diffraction angle of 5° to 80° . The morphological characteristics and elemental distribution were performed by scanning electron microscopy (SEM). The 3D morphological structures were measured by atomic force microscopy (AFM). Reflectance and transmittance spectra were performed by a 500-UV-Vis spectrophotometer in the wavelength range of 350–750 nm. The photovoltaic characteristics of the devices were measured using a solar simulator (AAA solar simulator) with a power density of 100 mW cm^{-2} .

3 Results and discussion

3.1 SEM, AFM, and XRD analysis of the prepared MgF_2 ARTF

To measure the different thicknesses of MgF_2 ARTF on FTO, we performed SEM of their cross-sections. The results are shown in Fig. 1a and S1.† The thickness of MgF_2 ARTF obtained by evaporation of 0.1, 0.5, and 1 g of MgF_2 powder is approximately 100, 330, and 560 nm, respectively. The elemental distribution of fluorine and magnesium further determines the location of MgF_2 ARTF on FTO, as shown in Fig. 1b, c and S1.† Surface morphology of MgF_2 ARTF on FTO is shown in Fig. 1d. We can see that the surface of MgF_2 ARTF possesses a lot of nanoscale island. In contrast, the SEM image of the pure FTO conductive glass substrate is shown in Fig. S2.† The elemental distribution of fluorine and magnesium on FTO is shown in Fig. 1e and f,

Fig. 1 Micro-nano structures and crystalline phases. (a) Cross-sections SEM images of 300 nm MgF_2 ARTF on FTO. (b) F and (c) Mg element mapping in cross-section. (d) Surface SEM image of 300 nm MgF_2 ARTF on FTO. (e) F and (f) Mg element mapping on MgF_2 ARTF surface. AFM topography images of FTO without (g) and with (h) MgF_2 ARTF. (i) XRD patterns of FTO without and with MgF_2 ARTF.

respectively. The uniform distribution of fluorine and magnesium shows that MgF_2 ARTF has a good coverage on FTO. The results of elemental content ($\text{F/Mg} = 2.10$) show that the elemental proportions are consistent with the molecular formula of MgF_2 , as shown in Fig. S3.† In addition, the elemental content was further analyzed by XPS. The results are shown in Fig. S4.† We calculated the atomic ratio of F and Mg to be 2.11 by Thermo Avantage software, which is also consistent with the molecular formula of MgF_2 .¹⁶ To determine the undulation of MgF_2 ARTF surface, atomic force microscopy (AFM) experiments were performed on the surface of FTO without (Fig. 1g) and with (Fig. 1h) MgF_2 ARTF, and the morphology was studied in a range of $3 \times 3 \mu\text{m}^2$. As can be seen in the 3D plot, the surface of amorphous MgF_2 ARTF possesses a lot of nano-scale pits. The undulation of MgF_2 ARTF surface is approximately 1.5 nm. The results of AFM are consistent with those of SEM. To determine the crystalline phase of MgF_2 ARTF, XRD was carried out, as shown in Fig. 1i. The XRD pattern of MgF_2 ARTF is similar to that of glass side of the substrate (as shown in Fig. 2a left), suggesting that the MgF_2 ARTF is amorphous. Amorphous MgF_2 do not have a periodic lattice arrangement, which will reduce the reflection caused by the crystal planes of the crystalline material. In contrast, the MgF_2 powder is crystalline phase. Compared with PDF standard cards, most of the peaks match with MgF_2 JCPDS card No. 41-1443 (Fig. S5†). These peaks located at 27.27, 35.21, 40.48, 43.87, 53.68, 56.25,

60.74, and 68.35° correspond to (110), (101), (111), (210), (211), (220), (002), and (301) planes of tetragonal MgF_2 , respectively.

3.2 Optical characteristics of MgF_2 ARTF

To study the optical characteristics of MgF_2 ARTF, ellipsometry and reflectance and transmittance spectra were measured. Diagrams of light path in FTO without and with MgF_2 ARTF are shown in Fig. 2a. The transmission spectra of MgF_2 ARTF with different thicknesses (approximately 100, 330, and 560 nm) were measured, as shown in Fig. S6.† From the results of the transmission spectroscopy, it can be seen that the transmittance of MgF_2 ARTF with a thickness of about 330 nm increases over the entire wavelength range (from 350 to 750 nm). Unless otherwise specified, 330 nm MgF_2 ARTF were used as samples for subsequent measurements and analyses. We measured the polarization state change (psi and delta) of the beam as it reflected from the surface of the MgF_2 ARTF by an M-2000VI spectroscopic ellipsometer (Fig. 2b) and calculated the simulated refractive index and extinction coefficient of the MgF_2 ARTF in the wavelength range of 350–750 nm (Fig. 2c). The refractive index of MgF_2 ARTF decreases gradually in the wavelength range of 410–750 nm (from 1.37 to 1.34). Theoretically, antireflective coatings can effectively reduce the reflection of light by the glass. Glass has a high refractive index of $n = 1.52$, so approximately 4.25% of the incident light on the surface of

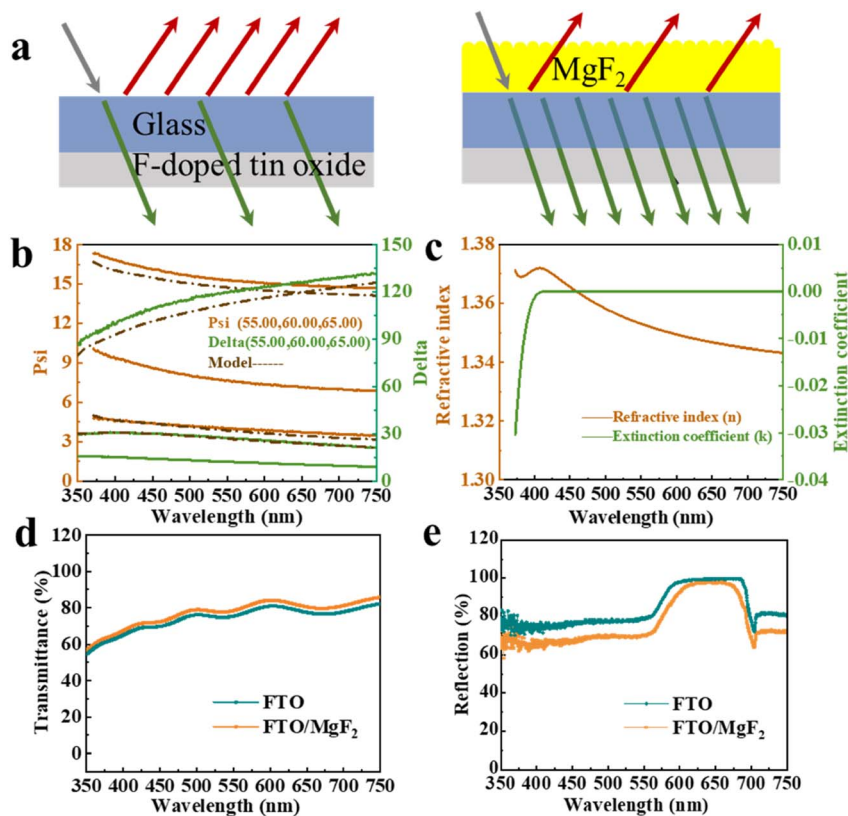

Fig. 2 Optical properties of FTO substrate without and with MgF_2 ARTF. (a) Diagram of light path in glass side of FTO without and with MgF_2 ARTF. (b) Change of polarization state when the beam is reflected from the surface of MgF_2 ARTF. (c) Refractive index and extinction coefficient of MgF_2 ARTF on FTO. Transmission (d) and reflectance spectra (e) of FTO substrate without and with MgF_2 ARTF.

FTO is reflected.¹⁷ The equivalent interfacial reflectance of MgF₂ ARTF can be calculated by the Fresnel equation:

$$R = \left(\frac{n_0 - n_f}{n_0 + n_f} \right)^2 = \left(\frac{1 - 1.35}{1 + 1.35} \right)^2 = 0.022$$

where R is the interface refractive index, n_0 is the refractive index in the air with a general value of 1, and n_f is the refractive index of the effective material (MgF₂ ARTF).¹⁸ Thus, approximately 2.20% of the incident light on the surface of MgF₂ ARTF is reflected. The optical properties (transmittance and reflectivity) of the MgF₂ ARTF on FTO were measured from 350 to 750 nm. As can be seen from Fig. 2d and e, the transmittance of FTO with MgF₂ ARTF is higher than that of bare substrate, the reflectance of FTO with MgF₂ ARTF is lower than that of the bare substrate, especially in the range of 400 to 750 nm (BaSO₄ as back plate for measurement of reflectivity). The above results indicate that MgF₂ ARTF can reduce light reflection on the surface and increase light transmission into the device, which will help to increase the short-circuit current density and result in improving the PCE.

3.3 Effect of MgF₂ ARTF on performance of inverted PSCs

To evaluate the performance of the MgF₂ ARTF, they were deposited on top of the inverted PSCs by VET and their performance were measured. The process of preparing invert PSCs is described in the experimental section. The cross-sectional structure and element mapping of inverted PSCs is shown in Fig. 3a. The position of each layer is consistent with

that of the detected feature element. The thickness of Au, BCP/PC₆₁BM, perovskite, and NiO_x is approximately 160, 50, 500, and 35 nm, respectively. The schematic diagram of MgF₂ ARTF on inverted PSCs is shown in Fig. 3b. The PCE of the devices was measured under 100 mW cm⁻² light intensity. The PCE of inverted PSCs without and with MgF₂ ARTF are 18.20 and 21.28%, respectively, as shown in Fig. 3c. The detailed photovoltaic parameters are as follows: (without MgF₂ ARTF) $J_{sc} = 21.37$ mA cm⁻², $V_{oc} = 1.09$ V, FF = 78.16%, (with MgF₂ ARTF) $J_{sc} = 24.89$ mA cm⁻², $V_{oc} = 1.09$ V, FF = 78.47%. The average photovoltaic parameters of the devices without and with MgF₂ ARTF for 20 cells are listed as follows: for the devices without MgF₂ ARTF: $V_{oc} = 1.08 \pm 0.02$ V, $J_{sc} = 21.45 \pm 2.53$ mA cm⁻², FF = 0.76 ± 0.02 , PCEs = $18.1 \pm 1.21\%$; for the devices with MgF₂ ARTF: $V_{oc} = 1.08 \pm 0.03$ V, $J_{sc} = 24.04 \pm 1.97$ mA cm⁻², FF = 0.76 ± 0.03 , PCEs = $19.8 \pm 2.27\%$. The significant improvement in PCE of the devices with MgF₂ ARTF is caused by the improvement in short-circuit current density. The significant improvement in PCE of the devices with MgF₂ ARTF is caused by the improvement in short-circuit current density. The IPCE curves of inverted PSCs are shown in Fig. 3d. Compared with that of the devices without MgF₂ ARTF, the IPCE of devices with MgF₂ ARTF increases significantly in the 375–840 nm range. The integrated current density from IPCE for devices without and with MgF₂ ARTF is 22.09 and 24.69 mA cm⁻², respectively. The results indicate that the MgF₂ ARTF increases the number of photon transmission and reduces those of photon reflection. In addition, the enhancement of photocurrent density by MgF₂

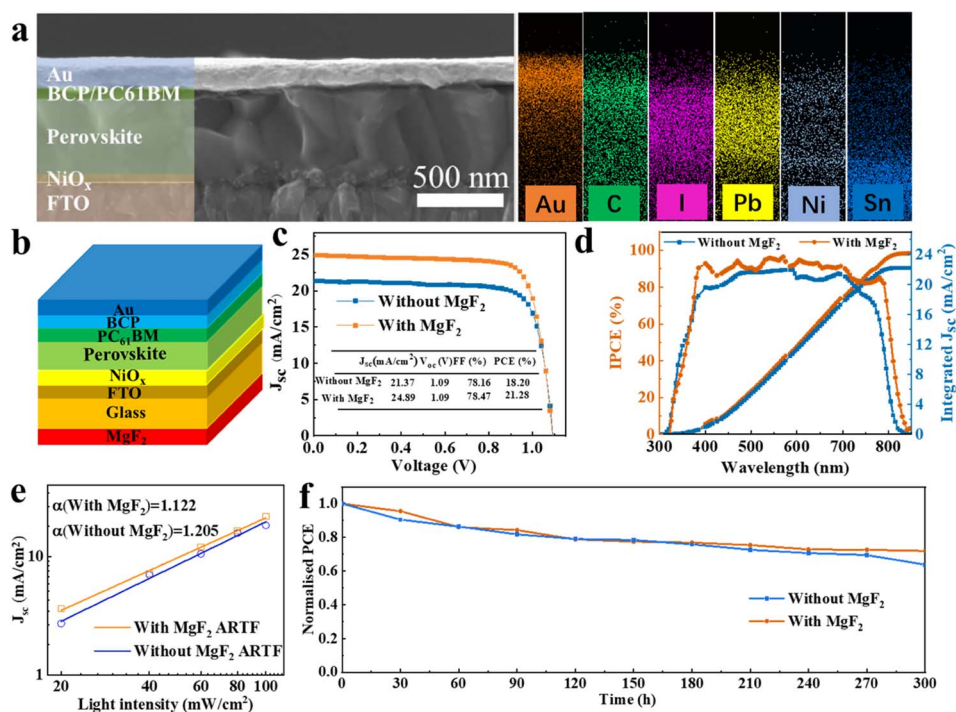

Fig. 3 Device structure and optoelectronic performance. (a) Cross-sectional SEM image and element mapping of inverted PSCs. (b) Structure diagram of MgF₂ ARTF on inverted PSCs. (c) The J - V curves of inverted PSCs without and with MgF₂ ARTF. (d) The IPCE and integrated current density curves of inverted PSCs without and with MgF₂ ARTF. (e) The effect of MgF₂ ARTF on photocurrent density under different light intensities. (f) The stability of inverted PSCs with MgF₂ ARTF under 100 mW cm⁻² light intensity for 300 h illumination.

ARTF under different light intensities was investigated. Fig. 3e shows the curves of the $J_{sc} \propto I^\alpha$, where α is the exponent, which should be close to 1, I is the light intensity. The exponent α (1.122) of inverted PSCs with MgF₂ ARTF is closer to 1 than that (1.205) without MgF₂ ARTF, suggesting that the non-radiation recombination has been suppressed and more carriers (photogenerated electrons and holes) are inclined to be transferred to the corresponding charge transport layer (PC₆₁BM and NiO_x).^{19–21} The MPP (maximum power point) tracking for 300 s was performed to evaluate both devices photostability, as shown in Fig. S7.† The current density of both devices stabilizes within the first 50 s. The current density is then stable from 50 to 300 s, indicating that both devices are photostable. Finally, the device with MgF₂-ARTF was measured for stability under 300 h illumination (100 mW cm⁻²), and the device without MgF₂-ARTF as reference. The results indicate that the PCEs of both devices are close to 70% of the initial PCE after 300 h illumination (Fig. 3f). The results indicate that MgF₂ ARTF only played a role in reducing reflection and increasing PCE, but did not play a role in increasing stability.

4 Conclusion

In this study, different thickness amorphous MgF₂ ARTF were prepared by VTE method and enhance PCE of inverted PSCs. The MgF₂ films have antireflective and transmissive effects on FTO conductive glass substrates. The surface of amorphous MgF₂ ARTF have a lot of nanoscale pits. The improvement in PCE of the devices with MgF₂ ARTF is attributed to the improvement in short-circuit current density. VTE method can be applied to the preparation of large area MgF₂ ARTF. The preparation methods and experimental conclusions in this paper can give ideas for other types of solar cells.
