# Structural, optical, magnetic properties and energy-band structure of $MFe_2O_4$ ( $M = Co, Fe, Mn$ ) nanoferrites prepared by co-precipitation technique

 Tran Dang Thanh,<sup>ab</sup> Tran Thi Ngoc Nha,<sup>b</sup> Tran Thi Ha Giang,<sup>a</sup> Pham Hong Nam,<sup>a</sup> Dang Ngoc Toan,<sup>cd</sup> Dinh Thanh Khan,<sup>e</sup> Do Hung Manh<sup>ab</sup> and Pham Thanh Phong<sup>fg</sup>

$MFe_2O_4$  ( $M = Co, Fe, Mn$ ) nanoparticles were successfully formed through the chemical co-precipitation technique. X-ray diffraction, scanning electron microscopy, and energy-dispersive X-ray analysis were used to investigate samples' structural properties. The investigated structural properties included phases formed, crystallite size, cation distribution, hopping length, bond length, bond angle, edge length, and shared and unshared octahedral edge length. Scanning electron micrographs of the prepared samples demonstrated well-defined crystalline nanoparticles. The grain diameter was 15, 9, and 34 nm for  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$ , respectively. The energy-dispersive X-ray analysis confirmed the existence of every element (Co, Fe, and O) and no discernible impurities in the samples. The optical properties were studied in detail through photoluminescence (PL) spectroscopy and Raman spectroscopy. The presence of active modes in Raman spectra confirmed the spinel structure of the  $MFe_2O_4$  nanoparticles. The direct bandgap energy estimated through UV-visible spectroscopy was about 2.59–2.64 eV, corresponding with the energy-band structures of the octahedral site (1.70 eV) and the tetrahedral site (0.9 eV). This result was further confirmed by PL emission spectra. Based on Mie theory and UV-visible and PL spectral data, the mechanism of photothermal characterization for  $MFe_2O_4$  nanoparticles was determined. Investigating the changes in temperature of magnetic parameters including coercivity, squareness ratio, and saturation magnetization for  $MFe_2O_4$  samples showed the dominant influence of ion distribution and A–A, A–B, and B–B exchange interactions. This study also showed that strong anisotropy and weak dipolar interaction tended to increase the coercivity and squareness ratio of  $CoFe_2O_4$ . Conversely, weaker anisotropy and stronger dipolar interaction corresponded with the small coercivity and squareness ratio of  $Fe_3O_4$  and  $MnFe_2O_4$  samples.

## 1. Introduction

The needs of emerging industries require various multifunctional materials that can be applied in diverse applications.

Nanomaterials, especially nanosized spinel ferrites with the general formula  $MFe_2O_4$  ( $M =$  divalent cation), exhibit many outstanding properties in the fields of magnetism, conductivity, and optics. Thus, they are a potential candidate in various fields from the electronics industry to biomedicine.<sup>1–3</sup> In general, the cation distribution between the A-site and B-site of an  $AB_2O_4$  spinel structure decides the structural type of ferrites, *i.e.*, whether it is normal or inverse or mixed.<sup>4</sup> If all divalent  $M^{2+}$  ions occupy the tetrahedral site (A site) and the trivalent  $Fe^{3+}$  ions occupy the octahedral site (B site), one would have normal spinel ferrites, and the inverse spinel structure becomes possible only when all divalent ions occupy the B site. The trivalent  $Fe^{3+}$  ions can be equally divided between the A and remaining B sites.<sup>5,6</sup> Among nanoferrites,  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$  nanoferrites are excellent because of their unique physical properties and important applications.<sup>7</sup> Bulk  $CoFe_2O_4$ ,  $MnFe_2O_4$ , and  $Fe_2O_4$  ferrites are predominantly inverse spinel

ferrites in which  $\text{Co}^{2+}/\text{Fe}^{2+}/\text{Mn}^{2+}$  ions primarily occupy the B-site and  $\text{Fe}^{3+}$  ions are distributed equally among the A- and B-sites.<sup>8</sup> However, in most cases, the preparation methods and the reduced size of spinels to the nanometer scale, the degree of inversion of the crystal structure becomes different from that of their bulk counterparts. Thus, the cation distribution directly affects the mechanical, chemical, and physical characteristics of spinel ferrite nanoparticles (NPs). This issue is well documented in the literature.<sup>9</sup> However, owing to the cation exchange between tetrahedral and octahedral sites, the properties of some spinels become complicated; they are not the same even if they have the same chemical formula.<sup>10</sup> This is a result of the quantum-confinement effect and the strength between the two A and B sublattice interactions.<sup>10</sup> Therefore, controlling the fabrication parameters and choosing the appropriate sample-preparing method can confer beneficial properties for nanoferrite applications in engineering and biomedicine. The fabrication of  $\text{CoFe}_2\text{O}_4$  and  $\text{Fe}_3\text{O}_4$  NPs and most of their optical and magnetic properties have been thoroughly studied and are well documented.

Hunpratub *et al.*<sup>11</sup> synthesized  $\text{CoFe}_2\text{O}_4$  NPs through a co-precipitation method and investigated the effect of cation distribution on their magnetic properties. They found that the predicted net magnetic moment values of all samples corresponded with the decrease in migration of  $\text{Co}^{2+}$  and  $\text{Fe}^{3+}$  between A and B sites. This result agreed with those of Yadav *et al.*<sup>12</sup> and Kumar *et al.*<sup>13</sup> Besides cation distribution and particle size, they suggested that the noncollinear structure of spins on the surface also needs to be considered as an important factor affecting the magnetization of  $\text{CoFe}_2\text{O}_4$  NPs.

Ansari *et al.*<sup>14</sup> studied the structural, physical, chemical, electronic, and magnetic properties of solvothermally synthesized  $\text{CoFe}_2\text{O}_4$  NPs. In particular, they found a doublet peak of  $T_{2g}(1)$  mode for  $\text{CoFe}_2\text{O}_4$  with different sizes, consistent with the observation of Chandramohan *et al.*<sup>15</sup> Á. de Jesús Ruíz-Baltazar *et al.*<sup>16</sup> found that the  $T_{2g}(1)$ ,  $T_{2g}(2)$ , and  $E_g$  modes are located at 312, 545, and 667  $\text{cm}^{-1}$ , respectively, consistent with the strange modes at 453, 755, 870, and 950  $\text{cm}^{-1}$  for 40 nm-sized  $\text{Fe}_3\text{O}_4$ . They attributed the appearance of these unknown modes to iron oxides left over from the magnetite formation. However, many authors believe that the Raman characteristics of the inverse and mixed spinel structure are double peaks.<sup>17–19</sup> Therefore, 10 Raman peaks at most can be observed in  $\text{Fe}_3\text{O}_4$  NPs.

It is clear that the previous reports of  $\text{MFe}_2\text{O}_4$  only confined to analyze the structural, optical, magnetic, and the correlation between the cation distribution with the modification of its physical properties. In addition, in recent years, the  $\text{MFe}_2\text{O}_4$  superparamagnetic nanomaterials were investigated for magnetic hyperthermia therapy. As a whole, this confirmed a fact that the role of dipolar interaction in the magnetic property were not investigated at length for  $\text{MFe}_2\text{O}_4$  nanoferrites *via* the co-precipitation method. Therefore, an intention was carried out to study the above said property for  $\text{MFe}_2\text{O}_4$  nanoferrites.

The photothermal effect in  $\text{Fe}_3\text{O}_4$  NPs and its process based on photoluminescence emission in the near-infrared (NIR) region are attracting scientific research attention. Sadat *et al.*<sup>20</sup>

used PL emission spectra in the NIR region and UV-visible (UV-Vis) spectra to establish the mechanism for interpreting the photothermal effect in (PAA)/ $\text{Fe}_3\text{O}_4$ , PS/ $\text{Fe}_3\text{O}_4$ , and Si/PS/ $\text{Fe}_3\text{O}_4$  NPs. Zhao *et al.*<sup>21</sup> studied the photothermal effect of  $\text{Fe}_3\text{O}_4$  NPs in solution and thin-film forms under the influence of white light and NIR laser irradiation. Interestingly, they obtained a stronger photothermal effect for  $\text{Fe}_3\text{O}_4$  under the stimulation of white-light irradiation. Their results are also explained based on PL and UV-Vis spectra and energy bands structure. However, the energy bands structure of ferrites is still a subject of debate. In general, the relatively complex electronic structure of transition metals has led to various confusing interpretations of the optical and magneto-optical Kerr spectra for ferrites owing to different assignments of the observed transitions.<sup>22</sup> Specifically, the photothermal effect mechanism of  $\text{CoFe}_2\text{O}_4$  and  $\text{MnFe}_2\text{O}_4$  NPs has not yet been studied.

Recently, we have synthesized and determined the elastic parameters and nanocrystalline size of spinel ferrites  $\text{MFe}_2\text{O}_4$  (M = Co, Fe, Mn, and Zn) through X-ray diffraction and infrared spectroscopy analyses.<sup>23</sup> In the present work, we continued to fabricate and study the structural, optical, and magnetic characteristics of the hard magnetic  $\text{CoFe}_2\text{O}_4$  and the soft magnetic  $\text{Fe}_3\text{O}_4$  and  $\text{MnFe}_2\text{O}_4$  NPs. We focused on discussing the relationship between UV-Vis and PL spectra from building the energy-band structure diagram of the three samples, as well as the role of dipolar interaction in the magnetic property of  $\text{MFe}_3\text{O}_4$  NPs.

## 2. Experimental detail

### 2.1. Synthesis of $\text{MFe}_2\text{O}_4$ (M = Co, Fe, Mn)

The co-precipitation technique was used to synthesize  $\text{MFe}_2\text{O}_4$  NPs following a previous procedure.<sup>23</sup> Cobalt(II) chloride hexahydrate ( $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\geq 98\%$ ), iron(III) chloride hexahydrate ( $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ ,  $\geq 98\%$ ), manganese(II) chloride tetrahydrate ( $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ ,  $\geq 98\%$ ), ferrous chloride tetrahydrate ( $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ ,  $\geq 98\%$ ), sodium hydroxide (NaOH,  $\geq 98\%$ ) were purchased from Sigma-Aldrich, US. Each  $\text{MFe}_2\text{O}_4$  sample was prepared from 50 mL of mixed aqueous solution by dissolving required amounts of  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$  and  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  (for  $\text{CoFe}_2\text{O}_4$ ),  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$  and  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  (for  $\text{Fe}_3\text{O}_4$ ), and  $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$  and  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  (for  $\text{MnFe}_2\text{O}_4$ ) with 2 : 1 molar ratio of  $\text{Fe}^{3+}$  to  $\text{M}^{2+}$ , respectively. Chemical precipitation was achieved at room temperature under vigorous stirring by adding 200 mL of 2 M NaOH solution and mixing for 60 min at pH 11 to 13. Afterward, the black precipitate of each sample was cooled to room temperature, the precipitates were separated with a permanent magnet, and they were washed with deoxygenated distilled water until neutral pH. Finally,  $\text{MFe}_2\text{O}_4$  was washed with acetone and dried in an oven at 70 °C for 120 min. All steps of preparing  $\text{MFe}_2\text{O}_4$  nanoferrites are clearly illustrated in Fig. 1.

### 2.2. Characterization

The crystalline phase of the synthesized  $\text{MFe}_2\text{O}_4$  NPs was examined using a Rigaku X-ray diffractometer equipped with Cu

Fig. 1 Schematic for synthesis  $MFe_2O_4$  ( $M = Co, Fe, Mn$ ) nanoferrites using co-precipitation method.

$K\alpha$  ( $\lambda = 1.5406 \text{ \AA}$ ). The  $2\theta$  range of  $10^\circ$  to  $80^\circ$  and a step size of  $0.02^\circ$  with a dwell time of  $0.05 \text{ s}$  were used during the measurement. Morphology and particle size were analyzed by scanning electron microscopy (SEM; Hitachi S-4800). The chemical compositions of  $MFe_2O_4$  NPs were obtained by the energy-dispersive X-ray (EDX) analysis using a Hitachi S-4800 FESEM equipped with an EDX energy-dispersive spectroscopy attachment.

Optical properties were assessed by PL emission. Measurements were made at an excitation wavelength of  $310 \text{ nm}$  using a fluorescence spectrophotometer (Fluorolog 3 FL3-22; Horiba). Raman spectra were obtained using an XploRA PLUS Micro Raman spectrometer (Horiba) with a laser wavelength of  $785 \text{ nm}$  as an excitation source. UV-Vis spectroscopy (JASCO V-770) was used to determine the bandgap of  $MFe_2O_4$  NPs. A 3 T Physical Property Measurement System VersaLab (model VL173; USA) was used to analyze magnetic properties.

### 3. Results and discussion

#### 3.1. Structural characteristics of $MFe_2O_4$ NPs

Fig. 2 illustrates the X-ray diffraction (XRD) pattern and Rietveld refinement of  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$  compatible with the JCPDS card number of  $CoFe_2O_4$  (No. 156-5326),  $Fe_3O_4$  (No. 151-3304),  $MnFe_2O_4$  (No. 230-0618). Their patterns showed typical diffraction peaks assigned to the (111), (220), (311), (222), (400), (422), (511), (440), (620), and (533) planes of the cubic spinel structure with the  $Fd\bar{3}m$  space group of ferrites. No additional peaks arising from impurities were detected within the limits of XRD measurement. The goodness factor ( $\chi^2$ ) was less than 2, which lay within the confidence threshold ( $1 \leq \chi^2 < 2$ ), demonstrating high refinement reliability.

The experimental lattice constant ( $a_{exp}$ ), unit-cell volume ( $V$ ) and oxygen positional parameter ( $u$ ) were determined from Rietveld refinement and are listed in Table 1. The lattice

constant and oxygen positional parameter of  $Fe_3O_4$  were less than those of  $CoFe_2O_4$  and  $MnFe_2O_4$ , which was attributed to the redistribution of cations ( $Fe^{3+}$ ,  $Mn^{2+}$ , and  $Co^{2+}$ ) between the two interstitial sites.<sup>11,24</sup> Conversely, the disparity of the oxygen positional parameter with ideal value ( $u = 0.375 \text{ \AA}$ ) may be due to anion displacement from the ideal position to expand the tetrahedral interstices.<sup>25</sup> However, these experimental values were close to the values obtained for the ferrite system in the literature.<sup>26,27</sup>

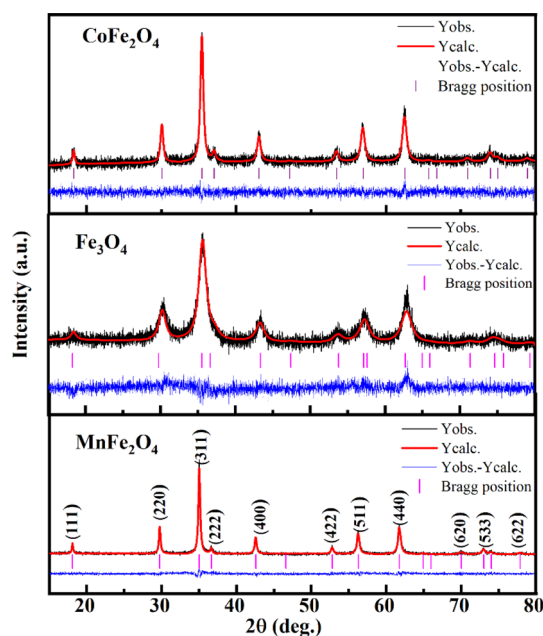

Fig. 2 The Rietveld refinement of XRD patterns for  $MFe_2O_4$  nanoparticles (observed – black line, calculated – red line and difference – blue line).

**Table 1** Cation distribution, experimental and theoretical lattice parameter ( $a_{\text{exp}}$ ,  $a_{\text{th}}$ ), unit cell volume ( $V$ ) and oxygen positional parameter ( $u$ ) mean ionic radii of A site ( $\bar{r}_{\text{A}}$ ) and B site ( $\bar{r}_{\text{B}}$ ), crystalline grain diameter ( $d$ ), grain size ( $D$ ) of  $\text{MFe}_2\text{O}_4$  nanoparticles

Sample	Cation distribution		$a_{\text{exp}}$ (Å)	$a_{\text{th}}$ (Å)	$V$ (Å <sup>3</sup> )	$u$	$\bar{r}_{\text{A}}$ (Å)	$\bar{r}_{\text{B}}$ (Å)	$d$ (nm)	$D$ (nm)
	A site	B site								
$\text{CoFe}_2\text{O}_4$	$\text{Co}_{0.08}^{2+}\text{Fe}_{0.92}^{3+}$	$\text{Co}_{0.92}^{2+}\text{Fe}_{1.08}^{3+}$	8.4093	8.4093	594.67	0.3806	0.4972	0.6910	14.6	14.7
$\text{Fe}_3\text{O}_4$	$\text{Fe}^{3+}$	$\text{Fe}^{2+}\text{Fe}^{3+}$	8.3628	8.3628	584.86	0.3762	0.4900	0.7125	7.0	9.0
$\text{MnFe}_2\text{O}_4$	$\text{Fe}^{3+}$	$\text{Mn}^{2+}\text{Fe}^{3+}$	8.4981	8.4981	613.71	0.3808	0.4900	0.7375	27.4	34.3

The cation distribution at the A and B sites was determined based on the assumption that the occupancies of the cations with a sum of cations at A site equal to 1 and a sum of cations at B site equal to 2 of the three samples are represented in Table 1. Thus, according to the cation distribution, the theoretical lattice constant ( $a_{\text{th}}$ ) was calculated using the following expression:<sup>11,26,28</sup>

$$a_{\text{th}} = \frac{8}{3\sqrt{3}} \left[ (r_{\text{A}} + R_{\text{O}}) + \sqrt{3} (r_{\text{B}} + R_{\text{O}}) \right] \quad (1)$$

where  $r_{\text{A}}$  and  $r_{\text{B}}$  are the ionic radius of tetrahedral and octahedral sites, respectively, and were calculated using the equations:

$$r_{\text{A}} = a_{\text{exp}} \sqrt{3} (u - 0.25) - R_{\text{O}} \quad (2a)$$

$$r_{\text{B}} = a_{\text{exp}} \sqrt{3} \left( \frac{5}{8} - u \right) - R_{\text{O}} \quad (2b)$$

where  $R_{\text{O}}$  is the radius of oxygen ion (1.38 Å). The ( $a_{\text{th}}$ ) values of three samples are listed in Table 1. The lattice constants  $a_{\text{th}}$  and  $a_{\text{exp}}$  well agreed with each other, indicating the migration of  $\text{Co}^{2+}$ ,  $\text{Mn}^{2+}$ , and  $\text{Fe}^{3+}$  ions into the tetrahedral and octahedral sites, respectively.<sup>28</sup>

Moreover, the mean cation radii at the tetrahedral ( $\bar{r}_{\text{A}}$ ) and octahedral sites ( $\bar{r}_{\text{B}}$ ) were determined based on the following cation distribution:

$$\bar{r}_{\text{A}} = C(\text{M}_{\text{A}}^{2+}) \cdot r(\text{M}_{\text{A}}^{2+}) + C(\text{Fe}_{\text{A}}^{3+}) \cdot r(\text{Fe}_{\text{A}}^{3+}) \quad (3a)$$

$$\bar{r}_{\text{B}} = \frac{C(\text{M}_{\text{B}}^{2+}) \cdot r(\text{M}_{\text{B}}^{2+}) + C(\text{Fe}_{\text{B}}^{3+}) \cdot r(\text{Fe}_{\text{B}}^{3+})}{2} \quad (3b)$$

where  $C$  is the ionic concentration at the tetrahedral and octahedral sites;  $r(\text{M}_{\text{A}}^{2+})$  are the ionic radii of  $\text{Co}^{2+}$  (0.58 Å) and  $\text{Fe}^{3+}$  (0.49 Å) ions in the tetrahedral sites, respectively;  $r(\text{M}_{\text{B}}^{2+})$ ,  $r(\text{Fe}_{\text{B}}^{3+})$  are the ionic radii of  $\text{Co}^{2+}$  (0.745 Å),  $\text{Mn}^{2+}$  (0.83 Å),  $\text{Fe}^{2+}$  (0.78 Å), and  $\text{Fe}^{3+}$  (0.645 Å) ions in the octahedral sites, respectively.<sup>29</sup> The  $\bar{r}_{\text{A}}$  and  $\bar{r}_{\text{B}}$  values of three samples are shown in Table 1. The average ionic radius of the tetrahedral site was reduced whereas the average ionic radius of the octahedral site increased in the order  $\text{Co} > \text{Fe} > \text{Mn}$  ions in  $\text{MFe}_2\text{O}_4$ . This finding was because  $\text{Fe}^{3+}$  ions (0.49 Å) with a smaller ionic radius were replaced by  $\text{Co}^{2+}$  ions (0.58 Å) with a larger ionic radius. Conversely, in (B) sites, all  $\text{Mn}^{2+}$  ions (0.83 Å) and  $\text{Fe}^{2+}$  ions (0.78 Å) with larger ion radii migrated to the B site, so the average ion radius of the B site increased.

The hopping length ( $L_{\text{A}}$  and  $L_{\text{B}}$ ), tetrahedral and octahedral bond lengths ( $d_{\text{AO}}$  and  $d_{\text{BO}}$ ), tetrahedral edge length ( $d_{\text{AOE}}$ ), and shared and unshared octahedral edge length ( $d_{\text{BOE}}$  and  $d_{\text{BOEU}}$ ) of the three samples were computed according to the equations below,<sup>28,30,31</sup> and the results are listed in Table 2.

$$L_{\text{A}} = 0.25a_{\text{exp}}\sqrt{3} \quad (4a)$$

$$L_{\text{B}} = 0.25a_{\text{exp}}\sqrt{2} \quad (4b)$$

$$d_{\text{AO}} = a_{\text{exp}}\sqrt{3} \left( u - \frac{1}{4} \right) \quad (5a)$$

$$d_{\text{BO}} = a_{\text{exp}} \left( 3u^2 - \frac{11}{4}u + \frac{43}{64} \right)^{1/2} \quad (5b)$$

$$d_{\text{AOE}} = a_{\text{exp}}\sqrt{2} \left( 2u - \frac{1}{2} \right) \quad (6a)$$

$$d_{\text{BOE}} = a_{\text{exp}}\sqrt{2}(1 - 2u) \quad (6b)$$

$$d_{\text{BOEU}} = a_{\text{exp}} \left( 4u^2 - 3u + \frac{11}{16} \right)^{1/2} \quad (6c)$$

In ferrites, the distances between intrinsic ions (cation–anion and cation–cation distances) and bond angles between metal ions directly affect the strength of the magnetic exchange interactions, thus, to gain deeper insight into the magnetic properties of the samples, the inter-ionic length and bond angles between ions were calculated, and results are provided in Tables 3 and 4. The interionic distances were determined using relations,<sup>32–35</sup>

$$p = a_{\text{exp}} \left( \frac{5}{8} - u \right) \quad (7a)$$

$$q = a_{\text{exp}}\sqrt{3} \left( u - \frac{1}{4} \right) \quad (7b)$$

$$r = a_{\text{exp}}\sqrt{11} \left( u - \frac{1}{4} \right) \quad (7c)$$

$$s = a_{\text{exp}}\sqrt{3} \left( \frac{u}{3} + \frac{1}{8} \right) \quad (7d)$$

for cation–anion length,

**Table 2** Hopping length ( $L_A$  and  $L_B$ ), tetrahedral bond length ( $d_{AO}$ ), octahedral bond length ( $d_{BO}$ ), tetrahedral edge length ( $d_{AOE}$ ), shared octahedral edge length ( $d_{BOE}$ ), unshared octahedral edge length ( $d_{BOEU}$ ) of  $MFe_2O_4$  nanoparticles

Sample	Hopping length		Edges				
	$L_A$ (Å)	$L_B$ (Å)	$d_{AO}$ (Å)	$d_{BO}$ (Å)	$d_{AOE}$ (Å)	$d_{BOE}$ (Å)	$d_{BOEU}$ (Å)
CoFe <sub>2</sub> O <sub>4</sub>	3.641	2.973	1.902	2.056	3.106	2.840	2.975
Fe <sub>3</sub> O <sub>4</sub>	3.621	2.957	1.828	2.081	2.985	2.928	2.957
MnFe <sub>2</sub> O <sub>4</sub>	3.680	3.005	1.925	2.076	3.144	2.865	3.006

$$b = \sqrt{2} \frac{a_{\text{exp}}}{4} \quad (8a)$$

$$c = \sqrt{11} \frac{a_{\text{exp}}}{8} \quad (8b)$$

$$d = \sqrt{3} \frac{a_{\text{exp}}}{4} \quad (8c)$$

$$e = \sqrt{3} \frac{3a_{\text{exp}}}{8} \quad (8d)$$

$$f = \sqrt{6} \frac{a_{\text{exp}}}{4} \quad (8e)$$

for cation–cation distances.

All these parameters of the three samples are given in Table 3. The change in values of these intrinsic distances well agreed with the unit-cell volume of the samples (Table 1).

The bond angles ( $\theta_1$ ;  $\theta_2$ ;  $\theta_3$ ;  $\theta_4$ ;  $\theta_5$ ) between metal ions were computed from values of cation–cation and cation–anion lengths using expressions.<sup>32–35</sup> Results are listed in Table 4.

$$\theta_1 = \cos^{-1} \left( \frac{p^2 + q^2 - c^2}{2pq} \right) \quad (9a)$$

$$\theta_2 = \cos^{-1} \left( \frac{p^2 + r^2 - e^2}{2pr} \right) \quad (9b)$$

$$\theta_3 = \cos^{-1} \left( \frac{2p^2 - b^2}{2p^2} \right) \quad (9c)$$

$$\theta_4 = \cos^{-1} \left( \frac{p^2 + s^2 - f^2}{2ps} \right) \quad (9d)$$

$$\theta_5 = \cos^{-1} \left( \frac{r^2 + q^2 - d^2}{2rq} \right) \quad (9e)$$

The values of  $\theta_1$ ,  $\theta_2$ , and  $\theta_5$  for Fe<sub>3</sub>O<sub>4</sub> exceeded those of CoFe<sub>2</sub>O<sub>4</sub> and MnFe<sub>2</sub>O<sub>4</sub>, whereas those of  $\theta_3$  and  $\theta_4$  for Fe<sub>3</sub>O<sub>4</sub>

**Table 4** Values of the interionic angles (in degrees) of  $MFe_2O_4$  nanoparticles

Sample	Bond angle				
	$\theta_1$	$\theta_2$	$\theta_3$	$\theta_4$	$\theta_5$
CoFe <sub>2</sub> O <sub>4</sub>	123.47	145.55	92.65	125.87	74.84
Fe <sub>3</sub> O <sub>4</sub>	124.87	152.52	90.55	125.39	78.82
MnFe <sub>2</sub> O <sub>4</sub>	123.40	145.23	92.75	125.90	74.65

were smaller than those of CoFe<sub>2</sub>O<sub>4</sub> and MnFe<sub>2</sub>O<sub>4</sub>. Generally, the greater decrease in  $\theta_3$  and  $\theta_4$  corresponded with stronger interactions in B–B; conversely, the greater increment in  $\theta_1$ ,  $\theta_2$ , and  $\theta_5$  corresponded with weaker interactions in A–B.<sup>33</sup> Fig. 3 illustrates the visualization of the arrangement of ion pairs with the intrinsic lengths between them and the angles formed by these lengths in the spinel structure. The influence of changing the value of bond angles on the magnetic properties of the samples is discussed in detail in the following section.

To minimize the total absolute value of errors, the average crystallite size ( $D$ ) of the prepared  $MFe_2O_4$  samples was calculated using the full width at half-maximum ( $\beta$ ) values and angle values corresponding with all peaks, as proposed by Monshi *et al.*<sup>34</sup>

$$\ln \beta = \ln \left( \frac{K\lambda}{D} \right) + \ln \left( \frac{1}{\cos \theta} \right) \quad (10)$$

The  $\ln \beta$  vs.  $\ln \left( \frac{1}{\cos \theta} \right)$  graphs of the samples are drawn in Fig. 4. The obtained average crystallite size ( $D$ ) was 14.5, 7.0, and 27.4 nm for CoFe<sub>2</sub>O<sub>4</sub>, Fe<sub>3</sub>O<sub>4</sub>, and MnFe<sub>2</sub>O<sub>4</sub>, respectively, as listed in Table 1. The large difference in crystal size between samples showed the role of pH and reaction time on phase formation and crystal size. This finding was consistent with that of Saf *et al.*<sup>28</sup> They found that CoFe<sub>2</sub>O<sub>4</sub> samples synthesized at low pH have smaller crystallite sizes with poor crystallinity,

**Table 3** Values of the interionic distances of  $MFe_2O_4$  nanoparticles

Sample	Me–O (Å)				Me–O (Å)				
	$p$	$q$	$r$	$s$	$b$	$c$	$d$	$e$	$f$
CoFe <sub>2</sub> O <sub>4</sub>	2.0554	1.9019	3.6419	3.6684	2.9731	3.4863	3.6413	5.4620	5.1496
Fe <sub>3</sub> O <sub>4</sub>	2.0807	1.8280	3.5003	3.6270	2.9567	3.4670	3.6212	5.4318	5.1211
MnFe <sub>2</sub> O <sub>4</sub>	2.0752	1.9253	3.6866	3.7082	3.0045	3.5231	3.6798	5.5197	5.2040

Fig. 4 Modified Scherrer for MFe<sub>2</sub>O<sub>4</sub> nanoparticles.

whereas CoFe<sub>2</sub>O<sub>4</sub> samples synthesized at high pH have a larger crystallite size with a greater degree of crystallinity.

### 3.2. FE-SEM and EDX of MFe<sub>2</sub>O<sub>4</sub> NPs

The morphology of MFe<sub>2</sub>O<sub>4</sub> NPs was examined by the FE-SEM technique, and results are shown in Fig. 5(a–c). Fig. 5 reveals particle agglomeration with spherical NPs and a narrow particle-size distribution. Analysis results of SEM images using ImageJ software demonstrated the average particle size to be 14.7, 9.0, and 34.3 nm for CoFe<sub>2</sub>O<sub>4</sub>, Fe<sub>3</sub>O<sub>4</sub>, and MnFe<sub>2</sub>O<sub>4</sub>, respectively. Experimental studies have determined the critical sizes for superparamagnetic (SPM) behavior of CoFe<sub>2</sub>O<sub>4</sub>, Fe<sub>3</sub>O<sub>4</sub>, and MnFe<sub>2</sub>O<sub>4</sub> NPs to be 10–17 nm,<sup>36</sup> 20 nm,<sup>37,38</sup> and 43 nm,<sup>39</sup> respectively. Therefore, our samples satisfy the conditions for the existence of the SPM state at temperature  $T > T_B$  and blocked state at temperature  $T < T_B$  (here  $T_B$  is a blocking temperature).

The values of the average particle sizes from SEM images well agreed with those of the average crystallite sizes determined from the XRD patterns. The structure of MFe<sub>2</sub>O<sub>4</sub> NPs was further investigated by EDX spectroscopy. The results are presented in Fig. 5(d–f). Co, Fe, Mn, and O elements were present without any impurity elements from precursors. As shown in the inset of Fig. 5(d–f), the observed atomic percentage of metal cations and anions determined from the average value of three different positions of each sample was close to the standard metal cation-to-anion ratio (3 : 4) of ferrites. This finding further confirmed that all precursors reacted very well with one another to finally form the desired nanoferrite samples.

### 3.3. Raman spectra of MFe<sub>2</sub>O<sub>4</sub> NPs

Raman spectroscopy measurements were performed at room temperature to further study the surface and structural properties of materials, and results are presented in Fig. 6(a). Calculations from group theory predict  $A_{1g} + E_g + 3T_{2g}$  Raman modes in the normal cubic spinel structure.<sup>40,41</sup> Thus, the phonon-mode assignment for our samples was conducted in accordance using the available literature.<sup>17,19,40–47</sup> The highest frequency  $A_{1g}$  mode above 600 cm<sup>-1</sup> was assigned to the symmetric breathing mode of oxygen atoms concerning Co, Fe, and Mn ions in the tetrahedral void (AO<sub>4</sub>).<sup>42</sup> The second-highest frequency  $T_{2g}(3)$  mode from 450 cm<sup>-1</sup> to below 600 cm<sup>-1</sup> was due to as either the antisymmetric breathing mode of the AO<sub>4</sub> unit<sup>40,43</sup> or to the asymmetric bending motion of oxygen bonded to the tetrahedral cation.<sup>44</sup> The  $T_{2g}(2)$  mode from 330 cm<sup>-1</sup> to below 480 cm<sup>-1</sup> was due to a translation along one direction of the lattice, with the cation and oxygen atoms moving in opposite directions.<sup>40,45</sup> The  $E_g$  mode from 140 cm<sup>-1</sup> to below 330 cm<sup>-1</sup> was ascribed to the symmetric bending motion of oxygen anions within the AO<sub>4</sub> unit.<sup>40</sup> The lowest frequency Raman-active mode  $T_{2g}(1)$  was a complete translation of the tetrahedral void within the spinel lattice.<sup>40,42,45</sup> However, all Raman modes were asymmetric (or dissociated). The deconvoluted Raman spectrum for all major peaks of the samples along with their fits are presented in Fig. 6(b–d), whereas parameters derived are summarized in Table 5. These results showed that each peak can be presented like a doublet, which was

Fig. 5 (a–c) HR-SEM image, particle size distribution histogram and (d–f) corresponding EDX spectra of  $MFe_2O_4$  nanoparticles.

characteristic of the inverse or mixed spinel structure,<sup>19,46,47</sup> similar to the peak positions reported for  $NiFe_2O_4$  and  $ZnFe_2O_4$  NPs.<sup>17</sup> This variation in the relative Raman intensities of  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$  was due to ionic-radius differences in  $Co^{2+}$ ,  $Fe^{2+}$ ,  $Fe^{3+}$ , and  $Mn^{2+}$ . Moreover, the downshifts and broadening of the Raman peaks in  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$  NPs primarily originated from the strain growth and quantum-confinement effect of optical phonons in nanosized crystalline particles.<sup>48</sup>

### 3.4. Optical properties and electronic band structure of $MFe_2O_4$ NPs

To investigate the optical-absorption properties of the materials, UV-Vis-NIR absorption spectra of the  $MFe_2O_4$  NP samples were measured using a spectrophotometer (JASCO V-770) within the wavelength range of 300 nm to 900 nm. Fig. 7

shows the absorbance spectra of  $MFe_2O_4$  NPs. As shown in Fig. 7, the  $Fe_3O_4$  NPs exhibited an absorbance peak at 390 nm, following the finding of Zhao *et al.*<sup>21</sup> Meanwhile, those of  $MnFe_2O_4$  NPs were about 410 nm, and a wide absorbance band was observed for  $CoFe_2O_4$  NPs. This result was due to the change in optical-energy bandgap and the effect of nanoferrites' surface roughness.<sup>48,49</sup> The absorbance spectra were related to the electronic structure and were thus used to determine the relation of crystallite size to the optical bandgap. The optical energy bandgap of  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$  NPs were evaluated using the Tauc model<sup>50</sup> with the help of UV-Vis data.

$$\alpha hv = A(hv - E_g)^n \quad (11)$$

where  $n$  represents the nature of transitions with  $n = 1/2$  for allowed direct transitions and  $n = 2$  for indirect transitions, respectively;  $A$  is a constant that depends on the transition

Fig. 6 (a) Experimental Raman spectrum under excitation wavelength of 785 nm and (b–d) Raman active modes fitted with cumulative fit are displayed for MFe<sub>2</sub>O<sub>4</sub> nanoparticles.

Table 5 Assigned Raman modes for MFe<sub>2</sub>O<sub>4</sub> nanoparticles

Sample	T <sub>2g</sub> (1) (cm <sup>-1</sup> )	T <sub>2g</sub> (1) (cm <sup>-1</sup> )	E <sub>g</sub> (cm <sup>-1</sup> )	E <sub>g</sub> (cm <sup>-1</sup> )	T <sub>2g</sub> (2) (cm <sup>-1</sup> )	T <sub>2g</sub> (2) (cm <sup>-1</sup> )	T <sub>2g</sub> (3) (cm <sup>-1</sup> )	T <sub>2g</sub> (3) (cm <sup>-1</sup> )	A <sub>1g</sub> (cm <sup>-1</sup> )	A <sub>1g</sub> (cm <sup>-1</sup> )
CoFe <sub>2</sub> O <sub>4</sub>	78.49	105.51	146.89	307.24	360.10	472.37	490.37	560.81	630.03	685.45

MnFe <sub>2</sub> O <sub>4</sub>	80.86	109.78	150.31	307.14	337.33	413.11	453.70	595.30	619.36	666.88

Fig. 7 Room temperature UV-Vis absorbance spectrum of MFe<sub>2</sub>O<sub>4</sub> nanoparticles.

probability, and  $E_g$  is the optical bandgap. Fig. 8(a–c) displays  $(\alpha hv)^2$  vs.  $hv$  for the samples. Direct bandgap values were obtained by extrapolating the linear regions of these plots along the X-axis. The obtained bandgap energy was found to be 2.63, 2.64, and 2.59 eV for the CoFe<sub>2</sub>O<sub>4</sub>, Fe<sub>3</sub>O<sub>4</sub>, and MnFe<sub>2</sub>O<sub>4</sub> NPs, respectively, showing a decrease in the bandgap from Fe<sub>3</sub>O<sub>4</sub> to MnFe<sub>2</sub>O<sub>4</sub>. The decrease in bandgap energy was due to the size effect and the redistribution of anion ions from octahedral to tetrahedral sites. The obtained direct bandgap value of CoFe<sub>2</sub>O<sub>4</sub> and Fe<sub>3</sub>O<sub>4</sub> NPs were comparable with previously reported

values.<sup>51–53</sup> Fig. 8(d–f) shows the plot of the absorption coefficient ( $\alpha$ ) against photon energy for the three samples based on the absorbance data from Fig. 7. The absorption coefficient  $\alpha$  is depicted by the relation<sup>54</sup>

$$\alpha = \alpha_0 \left[ \sigma \left( \frac{E - E_0}{k_B T} \right) \right] \quad (12)$$

where  $\alpha_0$ ,  $E$ , and  $E_0$  are the absorption coefficient, incident energy, and onset of absorption, respectively. Notably,  $\alpha_0$  and  $E_0$  depends on the nature of the material.  $E_u = k_B T / \sigma$  is specified as the Urbach energy (also known as Urbach “tail”), where  $\sigma$  is the steepness parameter and  $k_B$  is the Boltzmann constant. Generally, the Urbach energy is governed by the crystal defect originating from thermal fluctuations, impurities, and crystalline-lattice disordering.<sup>20,55</sup> The Urbach energy is determined from the reciprocal of the slope of the linear portion's fitting line in the  $\ln(\alpha)$  versus photon energy ( $hv$ ) plot. The Urbach energy values obtained for CoFe<sub>2</sub>O<sub>4</sub>, Fe<sub>3</sub>O<sub>4</sub>, and MnFe<sub>2</sub>O<sub>4</sub> were 0.94, 1.32, and 1.20 eV, respectively.  $E_u$  increased with decreased grain size, indicating that electrons experienced a larger extent of disorder while passing across the bandgap. Thus, the behavior of the optical bandgap was consistent with the characterization of Urbach energy. The  $E_u$  obtained for our samples also well agreed with those in the literature.<sup>21</sup>

To study the energy-transfer mechanism of MFe<sub>2</sub>O<sub>4</sub> NPs in detail, we proposed an energy-band structure model based on

Fig. 8 (a–c) Plot of  $(E\alpha)^2$  vs.  $(h\nu)$ , in which red line represents the experimental absorption spectra, and dashed black line is the fit to the linear portion of the data, where the intercept of that curve in the x-axis gives estimating the optical band gap and (d–f) the red line represents the experimental absorption curve, and dashed black line is the fit to the linear portion of the curve; and the Urbach energy and onset of absorption are calculated from the fitting for  $\text{MFe}_2\text{O}_4$  nanoparticles.

theoretical calculations from the literature<sup>20,21,56–60</sup> and the results of our PL and UV-Vis measurements. According to Camphausen *et al.*,<sup>56</sup> the energy gap between the O(2p) to the empty M(4s) in the 3d transition-metal oxides is about 6 eV, whereas Zaanen *et al.*<sup>57</sup> found that this bandgap ranges within 4–6 eV. Between these bands is the octahedral and tetrahedral crystal-field energies generated from the orbitals of 3d metals. The splitting energy between lower  $t_{2g}$  and higher  $e_g$  levels in an octahedral crystal field is  $\Delta_{cf,o} \sim 1.75$  eV, and those of lower e and higher  $t_2$  levels in a tetrahedral crystal field is  $\Delta_{cf,t} \sim 1.55$  eV.<sup>58</sup> Moreover, the energy gap between the  $t_{2g}$  level (octahedral crystal field) and e level (tetrahedral crystal field) and the valence band of O(2p), respectively, approaches 0.9 eV.<sup>22,59,60</sup> From the above analysis, the energy-band structure of  $\text{MFe}_2\text{O}_4$  NPs is illustrated in Fig. 9. Using this approach, the bandgap values for the  $\text{CoFe}_2\text{O}_4$  (2.63 eV),  $\text{Fe}_3\text{O}_4$  (2.64 eV), and  $\text{MnFe}_2\text{O}_4$  (2.59 eV) determined from the absorbance data (Fig. 8(a–c)) were consistent with the bandgap ( $\sim 2.65$  eV) between the O(2p) and  $e_g$  level of the octahedral site. Fig. 8(d–f) also shows that the onset of absorption was very close to the crystal-field splitting energy for the octahedral site (1.75 eV).

Sadat *et al.*<sup>20</sup> obtained the PL spectra for 10 nm to 5  $\mu\text{m}$ -sized  $\text{Fe}_3\text{O}_4$  NPs. They found three main peaks near 565 nm (2.2 eV), 690 nm (1.79 eV), and 840 nm (1.47 eV) when the samples were illuminated with laser light at a wavelength of 407 nm (3.05 eV). They suggested that the peak at 565 nm is due to the radiative recombination of mobile electrons from  $t_{2g} \rightarrow e_g$  on the octahedral site, the peak at 690 nm to the recombination of trapped

electrons from the octahedral site to O(2p), and the peak at 840 nm to the electron traps on the tetrahedral site. These observations were consistent with the energy-band structure that they proposed. However, Zhao *et al.*<sup>21</sup> observed only the peak at 674 nm (1.84 eV) for 10 nm-sized  $\text{Fe}_3\text{O}_4$  NPs illuminated with a laser of 449 nm (2.76 eV). This large difference may be due to the influence of the quantum-confinement effect originating from the nanoscale of particle size and the use of dissimilar excitation light when measuring the PL spectra of  $\text{Fe}_3\text{O}_4$ .

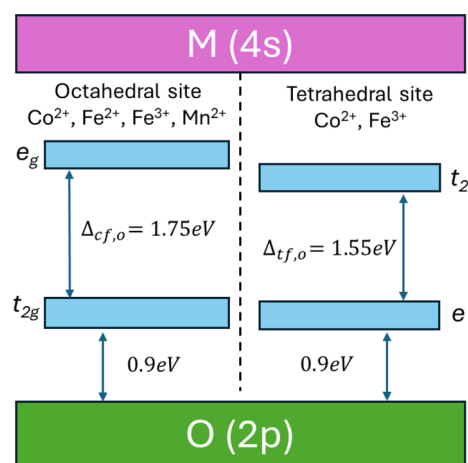

Fig. 9 Schematic of the energy bands for  $\text{MFe}_2\text{O}_4$  system.

PL measurements of  $\text{MFe}_2\text{O}_4$  NPs were performed using Xe light under an excitation wavelength of 310 nm (4.0 eV). Fig. 10(a) depicts the PL spectra of  $\text{CoFe}_2\text{O}_4$ ,  $\text{Fe}_3\text{O}_4$ , and  $\text{MnFe}_2\text{O}_4$  NPs. As shown in Fig. 10(a), the emission spectrum at each sample primarily comprised three dominated clear emission peaks at around 469 nm (2.64 eV), 728 nm (1.70 eV), and 823 nm (1.51 eV). The peak of UV emission at around 469 nm was consistent with the energy gaps caused by the  $e_g$  orbital of the octahedral site and the O(2p) level, whereas the visible peak at around 728 nm and NIR peak at around 823 nm were attributed to the crystal-field splitting energy for the octahedral and tetrahedral sites, respectively.

According to Mie's theory, to evaluate the photothermal performance of a material, the ratio of absorption efficiency ( $Q_{\text{abs}}$ ) to extinction efficiency ( $Q_{\text{ext}}$ ) needs to be analyzed and considered in detail, where  $Q_{\text{ext}}$  is the imaginary part of the complex refractive index, related to light absorption. Therefore, the absorption ( $Q_{\text{abs}}$ ), extinction ( $Q_{\text{ext}}$ ), and scattering ( $Q_{\text{sca}}$ ) efficiencies as a function of wavelength for  $\text{MFe}_2\text{O}_4$  NPs were calculated using equations:<sup>20,21</sup>

$$Q_{\text{ext}} = \frac{2}{x^2} \sum_{n=1}^{\infty} (2n+1) \text{Re}[a_n + b_n] \quad (13a)$$

$$Q_{\text{sca}} = \frac{2}{x^2} \sum_{n=1}^{\infty} (2n+1) [ |a_n|^2 + |b_n|^2 ] \quad (13b)$$

$$Q_{\text{abs}} = Q_{\text{ext}} - Q_{\text{sca}} \quad (13c)$$

in which  $a_n$  and  $b_n$  are the coefficients,  $x = \frac{2\pi n_{\text{med}} D}{\lambda_0}$  is the size parameter with  $D$  being the mean radius of the particles,  $n_{\text{med}}$  is the refractive index of the media, and  $\lambda_0$  is the vacuum wavelength. Using the code "Mie-Plot" written by Philip Laven,<sup>61</sup> the

numerical values of  $Q_{\text{ext}}$ ,  $Q_{\text{sca}}$ , and  $Q_{\text{abs}}$  were calculated as a function of wavelength for  $\text{MFe}_2\text{O}_4$  NPs and are shown in Fig. 10(b–d). Fig. 10(b) reveals that the extinction efficiency of  $\text{Fe}_3\text{O}_4$  NPs was mostly absorption-dominated, whereas those  $\text{CoFe}_2\text{O}_4$  and  $\text{MnFe}_2\text{O}_4$  NPs were not [Fig. 10(b) and (d)]. Thus,  $\text{CoFe}_2\text{O}_4$  and  $\text{MnFe}_2\text{O}_4$  had lower  $Q_{\text{abs}}/Q_{\text{ext}}$  than  $\text{Fe}_3\text{O}_4$  (1.00) and less efficient photothermal performance. This finding was consistent with the fact that smaller particles have higher surface area, so photothermal heating is more efficient.<sup>20</sup> However, the scattering efficiency of  $\text{MnFe}_2\text{O}_4$  exceeded those of  $\text{CoFe}_2\text{O}_4$  and  $\text{Fe}_3\text{O}_4$  owing to the difference in their grain size. This finding indicated good agreement with Mie's scattering theory because with decreased particle size, the pattern of the diffracted and scattered light spread away from the forward direction. Consequently, the larger grain size of  $\text{MnFe}_2\text{O}_4$  contributed to a greater scattering efficiency.

### 3.5. Magnetic properties of $\text{MFe}_2\text{O}_4$ NPs

Magnetic measurements of the  $\text{MFe}_2\text{O}_4$  NPs were performed at different temperatures. Fig. 11 shows the magnetization ( $M$ – $H$ ) loops ( $3 \text{ T} \leq H \leq 3 \text{ T}$ ) measured at 55, 100, 150, 200, 250, and 300 K. The magnetic parameters of all three samples including saturation magnetization ( $M_s$ ), remnant magnetization ( $M_r$ ), coercivity ( $H_c$ ), exchange bias field ( $H_{\text{ex}}$ ), effective anisotropy constant ( $K_{\text{eff}}$ ), and squareness ratio ( $R = M_r/M_s$ ) at various temperatures were extracted from these hysteresis loops and are listed in Table 6. For  $\text{CoFe}_2\text{O}_4$ , the value of  $M_s$  at 55 K (83.58  $\text{emu g}^{-1}$  or 3.51  $\mu_B$ ) was slightly higher than the theoretical value of ideal inverted structural ferrite (3.0  $\mu_B$  per F.U.),<sup>62,63</sup> bulk counterpart (80  $\text{emu g}^{-1}$ ),<sup>62,63</sup> and some nanosized  $\text{CoFe}_2\text{O}_4$  samples in literature.<sup>62</sup> The increment in  $M_s$  may be due to the distribution of Co and Fe ions at tetrahedral and octahedral sites compared with the ideal spinel structure. This was also confirmed by Ansari *et al.*<sup>14</sup> in oleic acid-coated  $\text{CoFe}_2\text{O}_4$ , that is,

Fig. 10 Photoluminescence spectrum (a), the wavelength dependence of extinction ( $Q_{\text{ext}}$ ), absorption ( $Q_{\text{abs}}$ ), scattering ( $Q_{\text{sca}}$ ) efficiencies (b–d) for  $\text{MFe}_2\text{O}_4$  system. The values are calculated based to the Mie theory using the complex refractive indices of the samples.

Fig. 11  $M(H)$  loops measured at different temperatures for the  $MFe_2O_4$  system.

even the organic coating does not significantly affect the high value of  $M_s$  in an inverted-structure  $CoFe_2O_4$ . For  $MnFe_2O_4$ ,  $M_s$  was  $88.87 \text{ emu g}^{-1}$  ( $3.67 \mu_B$  per F.U.) at 55 K, which was significantly higher than that of its bulk counterpart ( $3.3\text{--}4.5 \mu_B$  per F.U.).<sup>64–68</sup> Notably,  $Mn^{2+}$  has an isoelectronic configuration ( $3d^5$ ), which was zero crystal-field stabilization energy; thus, the influence of the inverse parameter on the magnetic properties of  $MnFe_2O_4$  was less pronounced than that of other spinel ferrites such as  $MgFe_2O_4$  or  $Fe_3O_4$ .<sup>69</sup> Consequently, similar to

$CoFe_2O_4$ , the  $M_s$  of  $MnFe_2O_4$  was larger than those of an inverted structural spinel ( $3.0 \mu_B$  per F.U.).<sup>64,65</sup> In contrast to the above two samples,  $M_s$  at 55 K ( $59.22 \text{ emu g}^{-1}$ ) of  $Fe_3O_4$  was smaller than that of its bulk counterpart ( $90 \text{ emu g}^{-1}$ ).<sup>70</sup> This was due to the spin-canting phenomena originating from the enhancement in the surface-to-volume ratio of the smaller-sized (9 nm)  $Fe_3O_4$ . This characteristic has been mentioned in most studies on the magnetic properties of nanosized  $Fe_3O_4$ .<sup>70</sup> The value of  $M_s$  in our samples was consistent with the change in the value of bond angles determined in Section 3.1. As shown in Table 5, the decrease in bond angle  $\theta_3$  and increase in length between the metal ions at the octahedral site and anion ( $p$ ) for  $Fe_3O_4$  indicated the weakening of the B–B interaction. Likewise, the bond angle  $\theta_5$  for  $Fe_3O_4$  increased, again confirming a weak interaction between A–B and A–A. Therefore, according to ref. 71,  $M_s$  of  $Fe_3O_4$  was smaller than that of the remaining samples. Table 6 reveals that the  $H_c$  of all samples monotonically decreased with increased temperature.

Furthermore, the coercivity values of  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$  at 55 K reached 9.13 kOe, 233 Oe, and 266 Oe, respectively. For  $CoFe_2O_4$ ,  $H_c$  was remarkably higher than that for bulk  $CoFe_2O_4$  ( $\sim 5 \text{ kOe}$  at 5 K),<sup>72</sup> whereas the low coercivity of  $Fe_3O_4$  and  $MnFe_2O_4$  indicated the soft magnetic nature of two these samples. The temperature variation of  $H_c$  for three samples can be fitted according to Keller's law, *i.e.*,

$$H_c = H_{c0}[1 - (T/T_B)^{1/2}] \quad (14)$$

where  $H_{c0}$  is coercivity at 0 K and  $T_B$  is the blocking temperature. The experimental data and fitting curves for  $CoFe_2O_4$ ,  $Fe_3O_4$  and  $MnFe_2O_4$  are revealed in Fig. 12.  $H_{c0}$  was 15 230, 356, and 389 Oe for  $CoFe_2O_4$ ,  $Fe_3O_4$  and  $MnFe_2O_4$ , respectively, and their  $T_B$  values were 328, 399 and 630 K, respectively. The good fitting according to Keller's law proved that three samples were non-interacting, randomly oriented spherical particles with cubic anisotropy. Thus, the relationship among coercivity, saturation

Table 6 Saturation magnetization ( $M_s$ ), remnant magnetization ( $M_r$ ), coercivity ( $H_c$ ), exchange bias field ( $H_{ex}$ ), effective anisotropy constant ( $K_{eff}$ ), squareness ratio ( $M_r/M_s$ ) and a magnetic grain size ( $D_m$ ) at various temperature of  $MFe_2O_4$  nanoparticles

Fig. 12 Temperature dependence of coercivity (solid circle) and the fitting line according to Kneller's law (solid black line) for  $MFe_2O_4$  samples.

magnetization, and effective anisotropy constant ( $K_{\text{eff}}$ ) can be given by the formula  $H_c = 0.64K_{\text{eff}}/M_s$ . The obtained  $K_{\text{eff}}$  values are listed in Table 6. The effective anisotropy constant values at 55 K were compatible with those of  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$  published in the literature.<sup>73–75</sup> Indeed, according to the Stoner–Wohlfarth (SW) model,<sup>76</sup> if  $R < 0.5$ , magnetostatic interactions between particles would dominate, whereas if  $R = 0.5$ , the particles would have no exchange-coupling and become randomly oriented uniaxial anisotropic ferromagnets. Finally,  $0.5 < R < 1.0$  confirmed the existence of exchange-coupling between particles. Therefore, from the low value of  $R$  ( $< 0.2$ ), we assumed that the interaction was much stronger between  $MnFe_2O_4$  and  $Fe_3O_4$  particles<sup>77</sup> and that the particle assembly was multidomain.<sup>71</sup> Accordingly, the SW model was less relevant for  $MnFe_2O_4$  and  $Fe_3O_4$  NPs.  $CoFe_2O_4$  is known to exhibit cubic magnetic anisotropy with the first crystalline magnetic anisotropy constant  $K_1 > 0$ , so the theoretical value of  $R$  should be 0.832. However,  $R$  in our  $CoFe_2O_4$  sample was smaller than the theoretical value, so we inferred that the contribution of surface spins to the value of  $K_{\text{eff}}$  was negligible. Thus, the SW model was less consistent for explaining the high values of  $H_c$  and  $K_{\text{eff}}$  in this case. These findings indicated that for our  $MFe_2O_4$  samples, surface anisotropy and dipole interactions were the main factors affecting  $H_c$  and  $K_{\text{eff}}$ .

To evaluate in more detail the role of these factors on the magnetic properties of the system, their magnetic grain volume ( $V_m$ ) is calculated by the formula  $V_m = 25k_B T_B / K_{\text{eff}}$ ,<sup>78</sup> where  $k_B$  is the Boltzmann constant. Subsequently, the diameters of

magnetic grains ( $D_m$ ) for the three samples, respectively, were obtained; results are listed in Table 6. Table 6 shows that  $D_m$  increased monotonically with temperature. Moreover, the  $D_m$  of both  $CoFe_2O_4$  and  $MnFe_2O_4$  samples were smaller than the average physical size, indicating the significant influence of canted surface spins around  $CoFe_2O_4$  and  $MnFe_2O_4$  NPs; whereas  $D_m$  of  $Fe_3O_4$  NPs were larger than the average size because of the collective behavior of several particle moments stimulated by the dipole–dipole interparticle interactions.<sup>73</sup> Thus, for  $CoFe_2O_4$  and  $MnFe_2O_4$  NPs, the  $K_{\text{eff}}$  mainly originates from the surface spins. Conversely, for  $Fe_3O_4$  NPs, surface spins do not provide  $K_{\text{eff}}$  but those induce magnetocrystalline anisotropy and dipole interaction. The strength of dipolar interparticle interactions for  $MFe_2O_4$  samples was calculated using the maximum dipolar field  $H_{\text{dip}}$  between nearest-neighbor particles through the relation  $H_{\text{dip}} = 2\mu/d^3$ , in which  $\mu$  is the particle moment ( $\mu = M_s \times V_m$ ) and  $d$  is the distance between the centers of two particles.<sup>79</sup> The  $H_{\text{dip}}$  parameters obtained for the samples are presented in Table 6. Notably,  $H_{\text{dip}}$  for  $Fe_3O_4$  was larger than that for the remaining samples, indicating that  $H_{\text{dip}}$  increased rapidly for larger-sized magnetic particles. Given that the magnetic particle size of  $Fe_3O_4$  was larger than that of  $MnFe_2O_4$  and  $CoFe_2O_4$ , more canted surface spins occurred around the  $CoFe_2O_4$  and  $MnFe_2O_4$  particles. Thus, the surface anisotropy in  $Fe_3O_4$  was weaker than that of  $MnFe_2O_4$  and  $CoFe_2O_4$ . Meanwhile, the smaller values of  $H_{\text{dip}}$  in  $CoFe_2O_4$  and  $MnFe_2O_4$  compared with that of  $Fe_3O_4$  confirmed that the magnetocrystalline anisotropy was weaker and the dipole–dipole interaction was stronger in  $CoFe_2O_4$  and  $MnFe_2O_4$ . However, a comparison of  $H_c$  and  $R$  for all three samples and the  $H_{\text{dip}}$  calculated for three samples suggested that the dipolar interactions between particles for  $MFe_2O_4$  NPs were predominant.  $Fe_3O_4$  and  $CoFe_2O_4$  particles synthesized with organic precursors also show similar behaviors.<sup>14,73,79–81</sup>

## 4. Conclusions

$MFe_2O_4$  ( $M = Co, Fe, Mn$ ) NPs were synthesized successfully using co-precipitation technique. The distribution of cations within interstitial sites was determined by X-ray diffraction, which showed that  $Co^{2+}$  and  $Fe^{3+}$  ions were distributed over both A and B sites for  $CoFe_2O_4$ . Conversely,  $Fe^{2+}$  and  $Mn^{2+}$  ions occupied the tetrahedral site only for  $Fe_2O_4$ , and  $MnFe_2O_4$ , respectively. The cation distribution within A and B sites induced changes in structural parameters, such as mean radii of tetrahedral and octahedral sites, edge lengths, bond lengths, and bond angles in the unit cell of  $MFe_2O_4$ . SEM images showed that  $MFe_2O_4$  NPs had a narrow size distribution with an average size of 14.7, 9.0, and 34.3 nm for  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$ , respectively. The observation of doublet phenomena of characteristic Raman peaks confirmed the feature of the inverse or mixed spinel structure for  $MFe_2O_4$  NPs. The optical energy bandgap calculated through UV-Vis spectroscopy was 2.63, 2.64, and 2.59 eV for  $CoFe_2O_4$ ,  $Fe_3O_4$ , and  $MnFe_2O_4$ , respectively. Based on the bandgap energy determined from UV-Vis and PL measurements, the energy-band structure diagram of  $MFe_2O_4$  was established, in which the bandgap energy determined from

the PL spectrum corresponded with the crystal-field splitting energy for the octahedral (1.70 eV) and tetrahedral (1.51 eV) sites. The mechanism of photothermal behavior of  $\text{MFe}_2\text{O}_4$  NPs was further determined based on the PL emission and UV-Vis spectra. Magnetic parameters such as coercivity, remanence, squareness ratio, and effective anisotropy constant were deduced from the magnetization loops under an applied magnetic field of  $3 \text{ T} \leq H \leq 3 \text{ T}$ . The change in magnetic saturation of  $\text{MFe}_2\text{O}_4$  samples was explained based on the cation distribution and A-A, A-B, and B-B interactions. The large coercivity and squareness ratio of  $\text{CoFe}_2\text{O}_4$  corresponded with strong effective anisotropy primarily due to the surface spins. Meanwhile, the smaller coercivity and squareness ratio of  $\text{MnFe}_2\text{O}_4$  and  $\text{Fe}_3\text{O}_4$  resulted from the weaker anisotropy and stronger dipolar interaction.
