This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Novel CO$_2$-stable dual phase membrane with high oxygen permeability

By cobalt-doping of the mixed conducting phase PSFC, a good combination of high CO$_2$ stability and high oxygen permeability is obtained for the 60 wt. % Ce$_{0.8}$Pr$_{0.2}$O$_{2-δ}$ - 40 wt. % Pr$_{0.6}$Sr$_{0.4}$Fe$_{0.5}$Co$_{0.5}$O$_{3-δ}$ (CP-PSFC) dual phase membrane, which suggests that CP-PSFC is as a promising membrane for industrial applications in the oxyfuel process for CO$_2$ capture.

CO$_2$ capture and storage technologies in power plants have gained attention worldwide since the combustion of fossil fuel is considered to be the main contribution to CO$_2$ emissions. Oxygen transporting membranes (OTMs) based on mixed electronic and ionic conductors, can supply 100 % purity oxygen to power stations for CO$_2$ capture according to the oxyfuel for CO$_2$ capture and storage. The oxyfuel concept involves the combustion of fossil fuels with an oxygen/exhaust gas mixture. The pure oxygen used in the oxyfuel process can be produced by the Linde cryogenic technique. However, by using OTMs, oxygen can be separated from air by using a part of the exhaust gas CO$_2$ as sweep gas. Oxygen production by using OTMs can reduce the costs by 35 % and save 60 % energy compared to the conventional cryogenic process. A part of the exhaust gas CO$_2$ is sequestered, another part recycled and used as sweep gas for the oxygen separation through the OTMs. Thus, the OTMs for CO$_2$ capture in oxyfuel process should have not only good stability in CO$_2$ atmosphere but also high oxygen permeation performance at elevated temperatures. Moreover, OTMs can be used in many promising potential applications, such as in high-purity oxygen production, in catalytic membrane reactors, and as cathodes in solid oxide fuel cells (SOFCs).

Among OTMs, many cobalt-based single phase perovskite-type membranes such as Ba$_{1-x}$Sr$_x$Co$_1-y$Fe$_y$O$_3$ exhibit high oxygen permeability since cobalt can provide a high concentration of oxygen vacancies in the perovskite lattice over a wide temperature range. However, under CO$_2$ atmosphere these membranes lose immediately their oxygen permeation flux, since the alkaline-earth metals on the A site of the perovskite framework form carbonates with CO$_2$. Recently, dual phase membranes with good structure stability and CO$_2$ resistance, made of a micro-scale mixture of well separated grains of the two phases of an oxygen ionic conductor and an electronic conductor, have attracted much attention for the application of the O$_2$ production in the oxyfuel concept. However, the low oxygen permeability of dual phase membranes needs to be improved to meet the industrial application requirements. Zhu et al. improved the oxygen permeability of their CO$_2$-stable dual phase membranes, such as Ce$_{0.8}$Sm$_{0.2}$O$_{1.9}$Pr$_{0.5}$Co$_{0.5}$O$_{2-δ}$ and Ce$_{0.8}$Sm$_{0.2}$O$_{1.92}$Sr$_{0.5}$Fe$_{0.5}$O$_{2-δ}$ by coating Co-containing porous layers on the membrane surface to enlarge the oxygen exchange surface. In our group, we have developed some novel Co-free CO$_2$-stable dual phase membranes, such as NiFe$_2$O$_4$-Ce$_{0.9}$Gd$_{0.1}$O$_{2-δ}$ (NF-CG), Fe$_2$O$_3$-Ce$_{0.9}$Gd$_{0.1}$O$_{2-δ}$ (F-CG) and Ce$_{0.9}$Pr$_{0.1}$O$_{2-δ}$-Pr$_{0.5}$Sr$_{0.5}$Fe$_{0.5}$O$_{2-δ}$ (CP-PSF). The CP-PSF membrane shows a good chemical stability under the harsh conditions of the POM reaction and in a CO$_2$ atmosphere at high temperatures. Thus, cobalt-doping of the PSF phase in the dual phase CP-PSF membrane can enhance the oxygen vacancy concentration in the membrane lattice, which should result in a combined good CO$_2$ stability and high oxygen permeability. In this paper, we present the novel dual phase membrane, 60 wt. % Ce$_{0.8}$Pr$_{0.2}$O$_{2-δ}$ - 40 wt. % Pr$_{0.6}$Sr$_{0.4}$Fe$_{0.5}$Co$_{0.5}$O$_{3-δ}$ (abbreviated as CP-PSFC) prepared via a one-pot sol-gel synthesis method. In this dual phase system, the CP phase is mainly for oxygen transport, and the PSFC phase for both electronic and ionic transport. The XRD pattern in Fig. 1 shows that after sintering at 1200 °C for 5 h in air, the dual phase CP-PSFC membrane consists of only the cubic fluorite CP phase (space group 225: Fm3m) and the orthorhombic distorted perovskite PSFC phase (space group 74: Imma). The phase stability of the dual phase CP-PSFC material against CO$_2$ was evaluated by in-situ XRD measurements (Fig. S2) between 30 and 1000 °C in an atmosphere of 50 vol% CO$_2$ / 50 vol% air. No carbonate formation was observed in the in-situ XRD patterns from 30 to 1000 °C, which is in good agreement with the in-situ XRD finding in previous reports of the CP-PSF and La$_{0.5}$Sr$_{0.5}$Co$_{0.5}$O$_{2-δ}$ under the similar experimental conditions. In this temperature range, the CP phase retains the cubic structure. Moreover, two phase transitions of the PSFC phase from the
orthorhombic to the rhombohedral symmetry at ca. 600 °C and from the rhombohedral to the cubic symmetry at ca. 800 °C could be observed. However, the PSF phase without Co in the dual phase CP-PSF powder retains the orthorhombic symmetry under the same conditions.\(^6\) The phase transition from rhombohedral to cubic symmetry at high temperatures is in agreement with the finding for the comparable materials La\(_{1-x}\)Sr\(_x\)Co\(_{0.5}\)Fe\(_{1.5}\)O\(_{4+\delta}\) and La\(_{1-x}\)Ca\(_x\)Co\(_{0.5}\)Fe\(_{0.5}\)O\(_{3+\delta}\).\(^7,\,\,8\) The formation of the cubic structure of the PSF phase at high temperatures is beneficial to the oxygen permeability.\(^7,\,\,17,\,\,20\) Thus, the dual phase CP-PSF material exhibits a stable co-existence of both the CP and the PSF phases and a good tolerance against CO\(_2\).

**Fig. 2** shows the scanning electron microscopy (SEM), backscattered SEM (BSEM), and energy-dispersive X-ray spectroscopy (EDXS) images of the dual phase CP-PSF membrane after sintered at 1200 °C for 5 h in air. SEM (Fig. 2a) indicates that the membrane is dense. In the BSEM (Fig. 2b, c) at different magnifications, the grains of the two phases are well distributed forming a 3-dimensional percolation network with clear grain boundaries, which is beneficial to the oxygen ion and electron transport through the membrane. The light grains in the BSEM are CP and the dark grains are PSF since the contribution of the backscattered electrons to the SEM signal intensity is proportional to the atomic number. The grain size of CP in these composite membranes is bigger than that of PSF. The same information of phase distribution is provided by the EDXS (Fig. 2d-f) of the membrane. Fig. 2d shows the color version EDXS of the membrane where the turquoise color (dark in BSEM) is an overlap of the Ce and Pr signals, whereas the orange color (light in BSEM) stems from an average of the Pr, Sr, Fe and Co signals. The EDXS elemental distributions of Ce in the CP grains (Fig. 2e) and Sr in the PSF grains (Fig. 2f) indicate the phase separation in the membrane and proof that no intermixing of Ce and Sr between the two phases exists.

The oxygen permeation fluxes through the dual phase CP-PSF membrane as a function of temperature with pure He and CO\(_2\) as sweep gases are shown in **Fig. 3**. For both the sweep gases He and CO\(_2\), the oxygen permeation flux increases with increasing temperatures. By increasing the temperatures from 800 to 1000 °C, the oxygen permeation fluxes range from 0.24 to 1.08 cm\(^3\)(STP)min\(^{-1}\)cm\(^{-2}\) for using He and from 0.11 to 1.01 cm\(^3\)(STP)min\(^{-1}\)cm\(^{-2}\) for using CO\(_2\) as sweep gas. If pure CO\(_2\) as sweep gas has been used, the oxygen permeation flux is only slightly lower than in the case when pure He was the sweep gas, which is in good agreement with the observation in previous reports.\(^13,\,\,14,\,\,21\) The reason of this experimental finding can be attributed to the weaker adsorptive interaction of He in comparison with CO\(_2\) with the membrane surface, as the influence of He on the oxygen exchange reaction is less than that of CO\(_2\).\(^12,\,\,14,\,\,22,\,\,23\) Furthermore, it is also found that the difference of the oxygen permeation flux between He and CO\(_2\) as sweep gases is bigger at lower temperatures and becomes smaller at higher temperatures, which can be ascribed to the decreasing adsorptive interaction with increasing temperatures. In comparison with the Co-free dual phase CP-PSF membrane at 950 and 1000 °C,\(^16\) the oxygen permeation fluxes of the Co-containing dual phase CP-PSF membrane are increased by approximately the factor of 3, which is a clear indication for an increased concentration of mobile oxygen vacancies by Co-doping which enhances significantly the oxygen permeability of the PSF phase.

The oxygen permeability of an OTM strongly depends on its composition, the membrane thickness, the coating of the membrane surface (catalytic coating or coating to enlarge the surface thus enhancing the exchange reaction), and the operation conditions (type of sweep gas, temperature, or the oxygen partial pressure). Table S1 contains the oxygen permeation fluxes of several OTMs evaluated with CO\(_2\) as sweep gas at ca. 950 °C. As shown in Table S1, our dual phase CP-PSF membrane exhibits the highest oxygen permeation flux compared to the other dual phase membranes. It should be noted that the fluxes measured on our dual phase CP-PSF membrane were obtained for a relative thick membrane (0.6 mm) without any coating on the membrane’s surface. It is believed that the oxygen permeability of our CP-PSF membrane can be further improved by reducing the membrane thickness as a hollow fiber membrane\(^23,\,\,24\) or by an asymmetric membrane,\(^25\) or by coating for a membrane surface enlargement.\(^12,\,\,13\)

**Fig. 4** presents the long-term oxygen permeation operation of two dual phase CP-PSF membranes M1 and M2. For CP-PSF membrane M1, when He is used as sweep gas at 950 °C, the oxygen permeation flux increases slowly during the activation time in the first 10 h. After this activation step, the oxygen permeation flux reaches steady-state with a constant value of 0.84 cm\(^3\)(STP)min\(^{-1}\)cm\(^{-2}\) (inset in Fig. 4). When pure CO\(_2\) was used instead of He as sweep gas, the oxygen permeation flux only slightly decreased to the lower value of 0.70 cm\(^3\)(STP)min\(^{-1}\)cm\(^{-2}\). This oxygen permeation flux was found to be constant during the whole oxygen permeation operation by using pure CO\(_2\) as sweep
gas at 950 °C for 400 h, when the operation temperature was elevated to 1000 °C, the oxygen permeation flux increased significantly to the highest value of 1.01 cm³(STP) min⁻¹ cm⁻² and was constant for at least 100 h. Whereas the CP-PSFC membrane M1 shows a phase transition from rhombohedral to cubic (Fig. S2) and a fast activation step over 10 h only at the higher temperature of 950 °C, when cooling the CP-PSFC membrane M2 from 950 to 800 °C, a phase transition from cubic to orthorhombic takes place (Fig. S2). After this phase transition, a slow activation step takes place over ca. 100 h at the lower temperature of 800 °C. As a result of (i) the phase transformation, and (ii) the lower permeation temperature, for the CP-PSFC membrane M2 with pure CO₂ as sweep gas at 800 °C, the oxygen permeation flux decreases slowly from 0.19 to 0.13 cm³(STP) min⁻¹ cm⁻² in the first 100 h. After this phase transformation and the activation step, the oxygen permeation flux reaches a steady-state for 200 h. For the membrane M1 and M2 after the long-term oxygen permeation operation, no carbonate formation was observed in the XRD patterns (Fig. S3 and S5). No carbon species enrichment was found on the strontium positions in the EDXS images of the membranes M1 and M2 surfaces (Fig. S6 and S7) and cross-sections (Fig. S4 and S8) which excludes a SrCO₃ formation. This long-term operations suggest that our dual phase CP-PSFC membrane exhibits an excellent stability in CO₂ and shows a high oxygen permeation performance.

In summary, we prepared a novel CO₂-stable dual phase 60 wt.% Ce₀.₅Pr₀.₅O₁.₅-δ/Pr₂O₃·Fe₂O₃·CoO₁.₅-δ (CP-PSFC) membrane with Co-doping of the PSF phase for a high oxygen permeability. Cobalt-doping of the PSF phase can enhance the oxygen vacancy concentration in the membrane lattice and stabilize the cubic structure above 800 °C which is beneficial for the oxygen permeability. The in-situ XRD and the long-term operations demonstrated that the CP-PSFC dual phase membrane shows a very good tolerance against CO₂. Moreover, the very high oxygen permeation flux of 0.70 and 1.01 cm³(STP) min⁻¹ cm⁻² were found to be constant at 950 and 1000 °C during the long-term operation over at least 400 h. The dual phase CP-PSFC membrane with excellent CO₂ stability and high oxygen permeation performance is a promising membrane material for industrial applications in the oxyfuel process for CO₂ capture.
