34 **Abstract**  
35

36 Molybdenum disulfide (MoS<sub>2</sub>) is an emerging material with some unique physical and electronic properties  
37 somewhat comparable to those of graphene. It was made with the use of a simple hydrothermal process, and  
38 has a layered structure similar to that of graphene. Also, it has peroxidase-like catalytic activity and is able  
39 to catalyze the oxidation of colorless peroxidase substrate, 3,3',5,5'-tetramethylbenzidine (TMB), in the  
40 presence of H<sub>2</sub>O<sub>2</sub> to produce a blue product. This reaction used MoS<sub>2</sub> as a useful peroxidase, which involved  
41 a colorimetric method for trace analysis of H<sub>2</sub>O<sub>2</sub> in water, e.g. lake waters. This method is uncomplicated,  
42 inexpensive and highly sensitive for H<sub>2</sub>O<sub>2</sub> in the 0.125 – 1.75 μM range (LOD: 0.08 μM). It is also quite  
43 stable in the presence of many common inorganic and organic potentially interfering compounds, e.g. metal  
44 ions as well as amino - acids and sugars.

Colorimetric method.

## 1. Introduction

Two-dimensional (2D) materials, such as graphene and transition metal dichalcogenides (TMDCs), have unique electronic, optical and mechanical properties.<sup>1-3</sup> Graphene has a single layer graphite structure, which has a large specific surface area, useful electronic and mechanical properties, and as a result, it has been widely applied in many research studies,<sup>4</sup> e.g. as a co-catalyst in photo-catalysis of the hydrogen evolution reaction (HER). Also, molybdenum disulfide (MoS<sub>2</sub>) with exposed edges has been recently reported as a promising electro-catalyst for the HER,<sup>5</sup> e.g. as a nano-tungsten carbide attached to graphene on a MoS<sub>2</sub> layer.<sup>6</sup> Additionally, the layered TMDC's cations have been used in a similar way,<sup>2,3</sup> e.g. as solid lubricants,<sup>7</sup> batteries<sup>8</sup> and catalysts.<sup>9</sup>

MoS<sub>2</sub> is one of the layered TMDC materials, which has a layered structure similar to that of graphene. It is composed of Mo-S-Mo groups, which are held together by weak van der Waals forces.<sup>10-12</sup> Preparative methods for mono- and multi-layered MoS<sub>2</sub> have been described, and include mechanical exfoliation, lithium intercalation and exfoliation, liquid phase exfoliation and chemical vapor deposition.<sup>1</sup> A mono-layer of MoS<sub>2</sub> is a semiconductor, which is potentially suitable for making sensors, transistors, optoelectronics and electroluminescent devices. It has a direct band gap and high mobility in contrast to the multilayered MoS<sub>2</sub>, which has an indirect band gap.<sup>13</sup> Compared to graphene, MoS<sub>2</sub> has attracted attention because of its unique physical properties, especially its complementary electronic behavior. Also, MoS<sub>2</sub> has been used as a solid lubricant in industry,<sup>14</sup> and it is a well-known catalyst for the production of hydrogen gas.<sup>10,15</sup> When MoS<sub>2</sub> is used as a co-catalyst with semiconductors such as TiO<sub>2</sub>,<sup>5</sup> CdS<sup>9</sup> and g-C<sub>3</sub>N<sub>4</sub>,<sup>16</sup> it enhances significantly the production of H<sub>2</sub> and the degradation of some pollutants.<sup>17</sup>

Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) plays an important role in many enzymatic reactions, as well as in essential biological processes such as the metabolism of proteins and carbohydrates or in the immune response process.<sup>18</sup> Consequently, an uncomplicated, inexpensive, rapid and sensitive analytical method for H<sub>2</sub>O<sub>2</sub> would be particularly welcome because it could be used for bio-assays, in chemical and pharmaceutical industries as well as in food security and environmental applications.<sup>19-23</sup> In this context, several biochemical methods for monitoring H<sub>2</sub>O<sub>2</sub> in blood have been developed, especially with the use of biosensors.<sup>24</sup> Other analytical methods for the analysis of this substance have been reported, including fluorescence,<sup>25</sup> cell imaging,<sup>26</sup> electrochemical<sup>14</sup> and colorimetric assays.<sup>27</sup> The colorimetric methods have been the ones, which fulfilled the above method criteria and consequently, such methods even now are important for bio-analysis

1 of H<sub>2</sub>O<sub>2</sub>. Many currently available colorimetric methods for the analysis of this analyte usually use  
2 peroxidase enzymes to catalyze the suitable enzymatic chromogenic substrate, TMB, to produce a blue  
3 product. An example of one such method commonly uses horseradish peroxidase (HRP).<sup>28</sup> However, these  
4 natural enzyme based methods generally need time-consuming and expensive preparation procedures, as  
5 well as analyte purification and strict storage conditions.<sup>27</sup> The use of nano-materials as efficient peroxidase  
6 mimetics are well known and include polypyrrole,<sup>27</sup> Fe<sub>2</sub>O<sub>3</sub>-graphene,<sup>29</sup> CuS,<sup>30</sup> ZnFe<sub>2</sub>O<sub>4</sub>,<sup>31</sup> FeS and FeSe.<sup>32</sup>  
7 ultra-small MoS<sub>2</sub> nanoparticles,<sup>14</sup> hemin-MoS<sub>2</sub> nanosheets,<sup>33</sup> carbon nanodots<sup>34</sup> and tungsten carbide  
8 nanorods.<sup>35</sup> The nanoparticle approach has gained traction in its application because the nanoparticles are  
9 cost-effective, easily obtained, relatively stable to biodegradation, and less vulnerable to denaturation.<sup>32</sup>  
10 Although electrochemical detection of H<sub>2</sub>O<sub>2</sub> based on MoS<sub>2</sub> has been reported,<sup>14,36</sup> such biosensors are  
11 limited by the lack of an ideal approach for immobilization of the enzymes on an electrode surface.<sup>37</sup>  
12 Hence, the aims of this work were: (1) to synthesise MoS<sub>2</sub> and investigate its properties when peroxidase  
13 substrate TMB and H<sub>2</sub>O<sub>2</sub> co-existed; (2) to use the MoS<sub>2</sub> as a catalyst for quantitative analysis of H<sub>2</sub>O<sub>2</sub> based  
14 on a colorimetric method and research its catalytic mechanism, and (3) to apply this new and simple method  
15 to analyse the H<sub>2</sub>O<sub>2</sub> in lake waters.

## 36 2. Experimental

### 37 2.1. Chemicals and materials

38 Sodium molybdate dihydrate (Na<sub>2</sub>MoO<sub>4</sub>·2H<sub>2</sub>O) and L-cysteine were purchased from Shanghai Chemical  
39 Reagent Co., Ltd. 3,3',5,5'-tetramethylbenzidine (TMB) and amino acids were purchased from Shanghai  
40 Sangon Biotech Co., Ltd. TMB was stored in a refrigerator at 4 °C. H<sub>2</sub>O<sub>2</sub> (30%), HCl (12 M) and  
41 terephthalic acid (TA) were purchased from Shanghai Sinopharm Chemical Reagent Co., Ltd. All the  
42 reagents and chemicals were Analytical Grade reagents and were used without further purification. The  
43 stored TMB (1.0 mM) solution was prepared by dissolving crystalline TMB (0.06 mg) in 50 mL 0.02 M HCl  
44 and then diluted to 250 mL with 0.02 M HCl. MoS<sub>2</sub> (0.1 mg mL<sup>-1</sup>) was prepared by dissolving 10.0 mg  
45 synthesized MoS<sub>2</sub> in 50 mL water and diluted to 100 mL. This solution was generally stable for two months  
46 at room temperature (20 °C). All the glassware were soaked in aqua-regia and thoroughly rinsed with doubly  
47 distilled water three times before use. The double-distilled water was used throughout this work.

## 2.2. Apparatus

Absorbance measurements were carried out on an Agilent 8453 UV–vis spectrophotometer (Agilent Technologies, Santa Clara, CA, USA). The scanning electron microscopy (SEM) images were made on a JSM–6701F microscope system (JEOL Co., Tokyo, Japan). Transmission electron microscopy (TEM) and energy dispersive X–ray spectroscopy (EDS), for measuring the structure and morphology of the resulting compounds, were carried out with the use of a JEM–2010 (JEOL Co., Japan), and the associated point and linear resolutions were found to be 0.23 nm and 0.14 nm, respectively. The accelerating voltage was set at 200 kV. The sample was placed on a carbon–coated copper grid by depositing a drop of the test solution on the grid. It was dried in air at room temperature. X–ray photoelectron spectroscopy (XPS) was performed on an ESCALAB 250Xi Microprobe (Thermo Scientific, USA) using 200 W mono–chromated Al K $\alpha$  radiation. X–ray diffraction (XRD) spectra were recorded with a Bede D1 high–resolution X–ray diffractometer system (Bede Co., UK). The fluorescence measurements were made on a Hitachi fluorescence spectrophotometer F–7000 (Hitachi Ltd., Tokyo, Japan).

## 2.3. Synthesis of MoS<sub>2</sub>

The layered MoS<sub>2</sub> was prepared by a hydrothermal synthesis.<sup>4,38</sup> NaMoO<sub>4</sub>·2 H<sub>2</sub>O (0.25 g) was dissolved in 25 mL water and 0.1 M HCl was added to this solution to adjust the pH to 6.5. Then, 0.5 g L<sup>–1</sup> L–cysteine and 75 mL water were added to the solution, which was then ultra–sonicated for 10 min. The mixture was transferred to a Teflon–lined, stainless steel autoclave (100 mL) and treated for 36 h at 200 °C. The mixture was allowed to cool and the black precipitate was collected by centrifugation (12000 rpm for 30 min). The black precipitate was then thoroughly washed several times with water, and vacuum dried at 80 °C for 24 h.

## 2.4. Peroxidase–like activity measurements

The peroxidase–like catalytic properties of MoS<sub>2</sub> were investigated by oxidizing the peroxidase substrate, TMB, in the presence of H<sub>2</sub>O<sub>2</sub>, and the formation of the blue product was tested. The control experiments were performed in the absence of H<sub>2</sub>O<sub>2</sub> or MoS<sub>2</sub> in the presence of the mixture, which contained 1.0 mM TMB (0.9 mL) and 0.1 M pH 4.0 acetate buffer (1.0 mL). The catalytic oxidation of TMB by MoS<sub>2</sub> (0.1 mg mL<sup>–1</sup>, 20  $\mu$ L) in the presence of H<sub>2</sub>O<sub>2</sub> (1.0 mM, 80  $\mu$ L) was also determined under the conditions described

1  
2 above; the absorbance change during each reaction above was recorded at 652 nm after 40 min.  
3  
4  
5

### 6 7 *2.5. Procedure for colorimetric analysis of H<sub>2</sub>O<sub>2</sub>*

8  
9 The procedure for the colorimetric analysis of H<sub>2</sub>O<sub>2</sub> was started by the addition of different concentrations of  
10 H<sub>2</sub>O<sub>2</sub> into 0.1 M pH 4.0 acetate buffer solutions (1.0 mL) in the presence of 1.0 mM TMB (0.9 mL) and  
11 0.1 mg mL<sup>-1</sup> MoS<sub>2</sub> (20 μL). Afterwards, the colorimetric reactions of the mixed solutions were heated at 30  
12 °C on a water bath with stirring for 40 min. were completed. Afterwards, the absorbance of each mixed  
13 solution was used for the analysis at 652 nm. The final concentrations of H<sub>2</sub>O<sub>2</sub> in the system varied from  
14 0.125 to 1.75 μM.

### 24 25 *2.6. Analysis of H<sub>2</sub>O<sub>2</sub> in aqueous samples*

26 H<sub>2</sub>O<sub>2</sub> was previously analysed in rain water and other different water samples,<sup>39–41</sup> and in this work , we  
27 verified the capability of the new peroxidase-like reagent, MoS<sub>2</sub> for the detection of H<sub>2</sub>O<sub>2</sub> in the water  
28 samples. These were collected from the Qianhu Lake, Nanchang University, and the collected sample was  
29 spiked with H<sub>2</sub>O<sub>2</sub>. After standing for 5 h, the water samples (about 300 mL) were filtered three times to  
30 remove any solid impurities, and the filtrate was centrifuged at 12000 rpm for 15 min to remove most of the  
31 microorganisms. Then, the water samples were diluted with the acetate buffer (0.1 M, pH 4.0), and spiked  
32 with H<sub>2</sub>O<sub>2</sub> at different concentrations. In the presence of 20.0 μL MoS<sub>2</sub> (0.1 mg mL<sup>-1</sup>), the 0.9 mL TMB (1.0  
33 mM) was added to the water samples (1.0 mL ) obtained above. These samples were diluted to 2.0 mL with  
34 water. Each sample was heated with stirring for 40 min at 30 °C on a water bath, and then their absorbance  
35 values were measured at 652 nm.

## 50 **3. Results and discussion**

### 51 52 *3.1. Characterization of the MoS<sub>2</sub>*

53 MoS<sub>2</sub> was prepared by a hydrothermal process (Section of 2.3).<sup>4,38</sup> Thus, MoS<sub>2</sub> was successfully synthesized  
54 in the solution-phase where Na<sub>2</sub>MoO<sub>4</sub> was reduced to MoS<sub>2</sub> by L-cysteine, which acted as the sulfide source  
55 as well as the reducing agent. It released H<sub>2</sub>S during the hydrothermal process (Eqn. 1 and 2 below, and  
56 Scheme 1A):  
57  
58  
59  
60

The structure and morphology of the synthesized MoS<sub>2</sub> were investigated with the use of XRD, SEM, TEM, EDS and XPS. XRD intensity plots of MoS<sub>2</sub> (Fig. 1A) showed a weak broad feature, which could be attributed to low crystallinity in the sample. Additionally, there were three diffraction peaks at (002), (100), (110) corresponding to 15.1°, 34.2° and 58.5°, respectively. The weak diffraction peak (002), suggested that the MoS<sub>2</sub> layers were stacked along the *c* axis. EDS of the MoS<sub>2</sub> (Fig. 1B) confirmed the presence of C, O, Mo and S, and the corresponding SEM images (Fig. 1C) suggested that the different MoS<sub>2</sub> layers were folded and tangled forming a multilayer morphology. Also, interconnected ripples and corrugations were clearly present, and they are consistent with the ready flexibility of the MoS<sub>2</sub> planes, thus producing structural deformation.<sup>42</sup> TEM images of MoS<sub>2</sub> (Fig. 1D) effectively supported the SEM observations. They revealed MoS<sub>2</sub> structures which displayed well-defined plate-like morphology, which was composed of large-scale, tightly stacked thin layers.

The XPS spectrum of MoS<sub>2</sub> (Fig. 1E) displayed the Mo and S elemental peaks as well as those of the Na, N, C and O elements, which confirmed the presence of the compounds involved in the hydrothermal synthesis. High-resolution XPS spectra for Mo 3d and S 2p were also collected (Figs. 1F and 1G), respectively. The Mo3d spectrum was deconvoluted into five single peaks; two peaks, located at 228.91 and 232.10 eV, were attributed to the binding energies of the Mo 3d<sub>5/2</sub> and Mo 3d<sub>3/2</sub> doublet peaks, respectively. The peaks were typical of the Mo<sup>4+</sup> oxidation state in MoS<sub>2</sub>, while the remaining peak at 226.22 eV corresponded well to the S 2s lines of MoS<sub>2</sub>.<sup>38,43</sup> In contrast, the S 2p region could be explained by the three 2 p<sub>3/2</sub>–2 p<sub>1/2</sub> spin-orbit doublets (Fig. 1G). The two peaks located at 161.8 and 163.15 eV could be assigned to the binding energies of the 2 p<sub>3/2</sub> and 2 p<sub>1/2</sub> lines of MoS<sub>2</sub> in the three S 2p doublets,<sup>43</sup> but the S 2p peaks, located at 161.8 eV, were consistent with the S<sup>2-</sup> oxidation state of sulfur.<sup>44</sup> Whereas, the peaks for S 2p<sub>3/2</sub> and 2 p<sub>1/2</sub> at 162.58 and 164.40 eV were probably indicative of a bridging S<sub>2</sub><sup>2-</sup> or poly-sulfides, S<sub>n</sub><sup>2-</sup>, which formed from the unsaturated S atoms.<sup>45</sup> The high-energy S 2p doublets, with the associated 168.02 eV (2p<sub>3/2</sub>) and 169.4 eV (2 p<sub>1/2</sub>) values, could be attributed to the S<sub>2</sub>O<sub>3</sub><sup>2-</sup> group.<sup>38</sup> The stoichiometric ratio between Mo and S estimated from the quantitative analysis of the Mo 3d<sub>5/2</sub> and S 2s peak intensities of the XPS spectra was close to 1:2; this result further confirmed the formation of MoS<sub>2</sub>.

### 3.2. Peroxidase-like activity of MoS<sub>2</sub>

The peroxidase-like activity of MoS<sub>2</sub> was investigated by studying the catalysis of the oxidation of the peroxidase substrate, TMB, in the presence of H<sub>2</sub>O<sub>2</sub>. Under acidic conditions, although the colorless solution of TMB was slowly oxidised by H<sub>2</sub>O<sub>2</sub>, it could only be rapidly oxidised to produce the blue colored product in the presence of the peroxidase-like action of the MoS<sub>2</sub> and H<sub>2</sub>O<sub>2</sub>. This blue product was the charge-transfer complex of the parent diamine and the diimine oxidation products, and it produced two absorption maxima at 370 nm and 652 nm (see [Scheme 1B](#)).<sup>46</sup> The UV-vis spectra did not discriminate between three of the four spectra ([Fig. 2](#)). Thus, TMB, TMB-H<sub>2</sub>O<sub>2</sub> and TMB-MoS<sub>2</sub> systems did not have any well-developed absorption peaks in the 500 to 800 nm range, while MoS<sub>2</sub>-TMB-H<sub>2</sub>O<sub>2</sub> system showed a strong absorption peak at 652nm; this was the typical peak of the oxidation products of TMB. Images of the different TMB solutions are displayed in the inset, [Fig. 2](#). Thus, the TMB solution remained effectively colorless when either MoS<sub>2</sub> or H<sub>2</sub>O<sub>2</sub> was present, i.e. no oxidation reaction occurred. However, this solution turned blue if both H<sub>2</sub>O<sub>2</sub> and the MoS<sub>2</sub> were added. These results indicated that MoS<sub>2</sub> showed peroxidase-like activity and effectively catalyzed the oxidation of TMB by H<sub>2</sub>O<sub>2</sub> in an acetate buffer.

### 3.3. Optimization of experimental conditions

The reaction conditions were optimized to establish the appropriate analytical conditions ([Fig. S1](#), [Supplementary Information](#)). The effect of reaction time on the catalytic activity of MoS<sub>2</sub> was investigated in the range of 10–70 min. Thus, the catalytic activity of MoS<sub>2</sub> increased with increasing reaction time from 10 min to 30 min ([Fig. S1A](#)). Then, the activity increase slowed and effectively stabilised from 30 min to 70 min. As a result 40 min was selected as the optimum reaction time. The effect of MoS<sub>2</sub> concentration in the 0.25 – 3.75 µg mL<sup>-1</sup> range ([Fig. S1B](#)), showed that the catalytic activity of the MoS<sub>2</sub> increased with the MoS<sub>2</sub> concentration up to 1.5 µg mL<sup>-1</sup>; above this concentration the catalytic activity decreased. In general, the experimental results indicated that the catalytic activity of the MoS<sub>2</sub> differed only slightly between 1.0 µg mL<sup>-1</sup> and 1.5 µg mL<sup>-1</sup>. Consequently, 1.0 µg mL<sup>-1</sup> MoS<sub>2</sub> was chosen for further experiments.

The effect of temperature was studied from 20 to 60 °C ([Fig. S1C](#)) and showed that the catalytic activity of MoS<sub>2</sub> increased with increasing temperature from 20 to 30 °C, but after this point, it decreased. Hence, 30 °C was chosen as the experimental temperature.

In the case of pH, the literature suggested that peroxidase-like activity for the catalysis of the oxidation of TMB by  $\text{H}_2\text{O}_2$  was much higher in acidic than neutral or basic solutions.<sup>29,30</sup> Thus, the acetate buffer was chosen as the optimum reaction medium for the reaction discussed above.

### 3.4. Mechanism of peroxidase-like activity of $\text{MoS}_2$

In the presence of  $\text{H}_2\text{O}_2$ ,  $\text{MoS}_2$  could catalyze the oxidation of TMB. Initially, during this reaction process some  $\text{H}_2\text{O}_2$  decomposes into the  $\cdot\text{OH}$  radicals and then, these will oxidize TMB so as to generate the corresponding blue oxidation product. To confirm this outcome, terephthalic acid (TA) was used as a fluorescent probe in the  $\text{MoS}_2$ - $\text{H}_2\text{O}_2$  system. Although TA does not fluoresce itself, on reaction with the  $\cdot\text{OH}$  radical, a strongly fluorescent compound, 2-hydroxy terephthalic acid (HTA) forms. The corresponding chemical equation is:<sup>47</sup>

Subsequently, each of the following solutions – (a)  $1.0 \mu\text{g mL}^{-1}$   $\text{MoS}_2$  without  $\text{H}_2\text{O}_2$ ; (b)  $50 \text{ mM}$   $\text{H}_2\text{O}_2$  without  $\text{MoS}_2$ ; (c)  $1.0 \mu\text{g mL}^{-1}$   $\text{MoS}_2$  and  $50 \text{ mM}$   $\text{H}_2\text{O}_2$  was treated with  $0.45 \text{ mM}$  terephthalic acid and heated in  $1 \text{ mL}$   $0.1 \text{ M}$  acetate buffer (pH 4.0) at  $30 \text{ }^\circ\text{C}$  for 12 h. A fluorescence spectrum of each solution was recorded at the excitation wavelength of  $324 \text{ nm}$  in the range of  $300 - 600 \text{ nm}$  (Fig. 3). These results showed that with sample (a) no fluorescence was recorded, with sample (b) a very small amount of fluorescence was emitted, but with sample (c) when  $\text{MoS}_2$  was added to the solution containing TA and  $\text{H}_2\text{O}_2$ , a strong fluorescence band was observed, i.e. enough of the  $\cdot\text{OH}$  radicals were produced to react with the non-luminescent TA to obtain the highly fluorescent HTA. These results strongly suggested that  $\text{MoS}_2$  could decompose  $\text{H}_2\text{O}_2$  to generate the  $\cdot\text{OH}$  radicals. This reaction was most likely to occur by the following mechanism: at first  $\text{H}_2\text{O}_2$  molecules were absorbed on the surface of the  $\text{MoS}_2$  and then they were activated by the bound  $\text{Mo}^{4+}$  to generate the  $\cdot\text{OH}$  radicals. These radicals were then stabilized by the  $\text{MoS}_2$  via a reaction process involving a partial electron exchange interaction.<sup>48</sup>

### 3.5. Detection of H<sub>2</sub>O<sub>2</sub> based on MoS<sub>2</sub>

An analytical method for H<sub>2</sub>O<sub>2</sub> in aqueous media was designed on the basis of the optimal experimental conditions discussed in the previous Sections. Thus, measured aliquots of H<sub>2</sub>O<sub>2</sub> at different concentrations were added to the acetate buffer solution (pH 4.0), which contained the TMB and MoS<sub>2</sub>. The different samples so produced were analyzed with the use of UV–vis absorption spectroscopy (Fig. 4), and the results (inset, Fig. 4) indicated that the absorbance *versus* H<sub>2</sub>O<sub>2</sub> concentration calibration plot at 652 nm was linear in the range of 0.125–1.75 μM. The regression equation was  $\Delta A = 0.0793 [\text{H}_2\text{O}_2] (\mu\text{M}) + 0.0338$ , correlation coefficient was 99.8% ( $n = 3$ ), and the limit of detection (LOD) for H<sub>2</sub>O<sub>2</sub> was 0.08 μM. These results were compared with those from previous methods for analysis of H<sub>2</sub>O<sub>2</sub> (Table 1). Importantly, the colorimetric method involving the MoS<sub>2</sub>, which mimicked the activity of the peroxidase, recorded the lowest range value, the lowest LOD and a convenient working temperature (30 °C). It should be noted that higher range values are of lesser importance because the sample can always be diluted. Thus, the mimic peroxidase compares well with the best 3–4 other peroxidase nano-mimetic substances,<sup>28,49,50</sup> and is arguably the best performer of the three measured variables (Table 1). Importantly, when the results from this work were compared with other kinds of layered MoS<sub>2</sub><sup>54</sup> systems for the detection of H<sub>2</sub>O<sub>2</sub>, they showed a lower limit of detection, and this result suggested that the novel peroxidase-like reagent (MoS<sub>2</sub>) showed better sensitivity and selectivity for the analysis of trace amounts of H<sub>2</sub>O<sub>2</sub>.

The new peroxidase-like reagent, MoS<sub>2</sub>, was also tested on H<sub>2</sub>O<sub>2</sub> spiked water samples (Table 2), and the recovery results were in the range of 94.9–107.2% (average: 99.3%) for three repeat samples. The relative standard deviation (RSD) values were in the range of 5.5–11.2% (average: 8.1%). Based on these results, the layer MoS<sub>2</sub> was able to analyse trace amounts of H<sub>2</sub>O<sub>2</sub> in water samples, and can be regarded as a new substance, which mimicked peroxidase activity.

### 3.6. Potentially interfering substances

In natural samples, there are often organic and/or inorganic substances, which may or may not interfere with the analysis of H<sub>2</sub>O<sub>2</sub> with the use of the novel MoS<sub>2</sub> layer method. Consequently, a large number of potentially interfering metal and non-metal ions as well as common organic compounds were tested in different amounts. These substances included: common metal and non-metal cations – K<sup>+</sup>, NH<sub>4</sub><sup>+</sup>, Ca<sup>2+</sup>, Mg<sup>2+</sup>, Zn<sup>2+</sup>, Ni<sup>2+</sup>, Ba<sup>2+</sup> and Al<sup>3+</sup> (all 10 mM), as well as organic compounds: glucose, fructose, sucrose, lactose, and

1  
2 various amino acids - aspartic acid (Asp), methionine (Met), phenylalanine (Phe), isoleucine (Ile), proline  
3  
4 (Pro), glycine (Gly), arginine (Arg), valine (Val), tryptophan (Trp), glutamate (Glu), leucine (Leu), histidine  
5  
6 (His), serine (Ser) and alanine (Ala) (all 50 mM). The effect of each of the potential interfering compound  
7  
8 was reflected in the bar graph (Fig. S2); each bar represented the concentration of H<sub>2</sub>O<sub>2</sub> ( $2.0 \times 10^{-6}$  mol L<sup>-1</sup>)  
9  
10 in the presence of an interfering substance and the results were represented as normalized spectral intensities  
11  
12 (A-A<sub>0</sub>)/A). In general, compared with the H<sub>2</sub>O<sub>2</sub> concentration without any interferents, there was only a  
13  
14 small interference effect observed in the presence of an interferent. The relative error was less than 5% in all  
15  
16 cases.  
17  
18

#### 21 4. Conclusions

22  
23 MoS<sub>2</sub> with its graphene-like layered structure was successfully synthesized with the use of an  
24  
25 environmentally effective and uncomplicated hydrothermal method. In so doing, it was found that the  
26  
27 layered MoS<sub>2</sub> had peroxidase-like, catalytic reactivity. The behavior of the MoS<sub>2</sub> was dependent on time, pH  
28  
29 and temperature similar to that noted for the peroxidase-like substances. Hence, MoS<sub>2</sub> could catalyze the  
30  
31 oxidation of peroxidase substrate, TMB, with H<sub>2</sub>O<sub>2</sub> to give a blue molecular product. It was found that the  
32  
33 peak maximum at 652 nm corresponding to the above blue substance produced a linear absorption *versus*  
34  
35 concentration plot, and this formed the basis for the colorimetric method for the detection of H<sub>2</sub>O<sub>2</sub> in the  
36  
37 0.125–1.75 μM range. The average %Recovery and %RSD values were 99.3% and 8.1%, respectively.  
38  
39 Importantly, the analytical performance of this novel method, which mimicked peroxidase, was compared  
40  
41 with several other peroxidase nanomimetics for the analysis of H<sub>2</sub>O<sub>2</sub> on the basis of three key experimental  
42  
43 variables – lowest Range value, LOD and Temperature. It arguably performed better. Also, this novel  
44  
45 method involving the MoS<sub>2</sub>, will be particularly suitable for the analysis of natural waters as well as for  
46  
47 environmental and bio-chemical samples.  
48  
49  
50
