Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about *Accepted Manuscripts* in the **Information for Authors**.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard <u>Terms & Conditions</u> and the <u>Ethical guidelines</u> still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

Oxidative Skeletal Rearrangement of 1,1'-Binaphthalene-2,2'-Diamines (BINAMs) via C–C Bond Cleavage and Nitrogen Migration: A Versatile Synthesis of U-Shaped Azaacenes

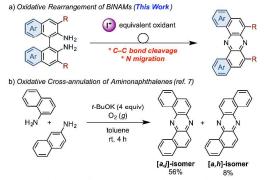

Youhei Takeda, $*^{a,b}$ Masato Okazaki^b and Satoshi Minakata $*^{b}$

An oxidative skeletal rearrangement of 1,1'-binaphthalene-2,2'-diamines (BINAMs) that involves the cleavage of a strong C-C single bond of the binaphthalene unit and the nitrogen migration has been discovered. The unprecedented rearrangement enables access to a series of U-shaped azaacenes otherwise difficult to prepare in a selective manner by classical methods. Moreover, physicochemical properties of the unique azaacenes have been comprehensively investigated.

Azaacenes, in which parts of C=CH fragments of acenes are formally replaced with isoelectronic imine (C=N) moieties, have been emerging as promising candidates for electrontransporting (n-type) materials in organic electronics.¹ The introduction of electronegative nitrogen atoms into π conjugated carbon frameworks allows for increasing electron affinities (EAs) to lower the barriers for electron injection from metal electrodes.² Furthermore, owing to the decrease in the number of C–H \cdots π contacts, azaacenes show a high propensity for adopting densely stacked packing-structures in the solid states, which favor carrier-transporting process.³ However, due to limited synthetic accessibility of azaacenes, the exploration of azaacene-based materials has fatally lagged behind those of acenes. Therefore, the development of novel synthetic approaches to azaacenes is fundamentally important from the viewpoints of not only synthetic chemistry but also material sciences. Traditionally, syntheses of azaacenes have exclusively relied on condensation/oxidation protocols starting from orthoarylenediamines and *ortho*-quinone derivatives.⁴ In this context, recently, a new synthetic protocol toward the preparation of azaacenes consisting of a Pd-catalyzed double amination of activated ortho-dichloroarenes with ortho-arylenediamines and a successive oxidation leading to *linear* azaacenes in an efficient manner, has been reported.⁵ On the other hand, Hiroto and Shinokubo have reported a DDQ-promoted oxidative

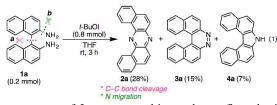

annulation of aromatic amines to selectively give kinked azaacenes and aza[7]helicenes depending on the conditions applied.⁶ Herein we present a new synthetic strategy to azaacenes based on a discovery of an unprecedented oxidative skeletal rearrangement of 1,1'-binaphthalene-2,2'-diamines (BINAMs) induced by an iodine-containing oxidant, which exclusively provides a series of dibenzo[a,j] phenazine-cored Ushaped azaacenes (Scheme 1a). As a relevant work, there is the single report that describes selective preparation of dibenzo[*a*,*j*]phenazine through an oxidative cross-annulation of α - and β -aminonaphthalenes mediated by a strong base (t-BuOK) under O₂ atmosphere (Scheme 1b).⁷ However, this known method intrinsically requires two regioisomers of aminonaphthalenes and suffers from the concomitant production of a constitutional [a,h]-isomer, thereby lacking the versatility as a synthetic approach to U-shaped azaacenes.

RSCPublishing

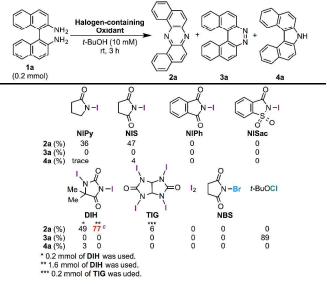

Scheme 1 Construction of dibenzophenazine-based U-shaped azaacenes

During our studies on the development of oxidative transformations of various amines utilizing iodine-containing oxidants,⁸ we serendipitously found out that the treatment of BINAM (1a) with *tert*-butyl hypoiodite (*t*-BuOI)⁹ produced dibenzo[*a,j*]phenazine (2a) in 28% yield along with the production of reasonably expected compounds $3a^{10}$ (15%) and $4a^{11}$ (7%) [eqn (1)].

The structure of 2a was unambiguously confirmed with the X-ray crystallographic analysis of its yellow single crystal (ESI[†]). Most importantly, the discovered transformation leading to **2a** formally involves the cleavage of the strong C(Ar)-C(Ar)bond [a in eqn (1)] of the binaphthyl unit (e.g., the bond dissociation energy (BDE) of Ph-Ph is as large as 118 kcal/mol)¹² without the aid of transition metal complexes¹³ and also involves the migration of a nitrogen atom [b in eqn (1)] to the adjacent carbon. Encouraged by this finding, we envisioned that the utilization of this unique rearrangement reaction would offer a versatile route to U-shaped azaacenes. To establish a novel approach to U-shaped azaacenes, reaction parameters were scrutinized to identify the conditions to selectively provide 2a (ESI[†]). Table 1 summarizes the effect of halogencontaining oxidants. To our delight, the use of N-iodolactams as an oxidant like NIS, NIPy, and DIH in t-BuOH selectively gave 2a in moderate yields along with trace amounts of 4a without affording 3a. The use of 8 mol equivalents of DIH gave 2a in 77% yield, although the role of excess of DIH is not clear at present. In sharp contrast, when N-chloro-containing oxidant (t-BuOCl) was used, diaza[5]helicene 3a was exclusively formed in a high yield (89%). Other types of oxidants like I₂, NBS, DDQ, $PhI(OAc)_2$, and MnO_2 failed to furnish 2a.

Table 1 Effect of halogen-containing oxidants^{a,b}

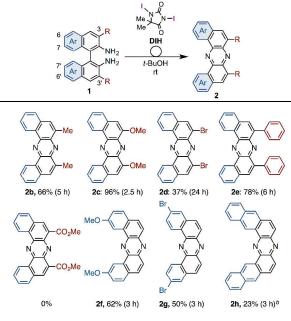

^{*a*} Reaction Conditions: **1a** (0.2 mmol) and oxidant (0.8 mmol) in *t*-BuOH (20 mL) at rt for 3 h. ^{*b*} Yields were determined by the integration of ¹H NMR charts of the crude products. ^{*c*} Isolated yield.

Having identified the optimal conditions for the rearrangement reaction, the scope and limitation of BINAM substrates were surveyed (Table 2). The treatment of BINAMs bearing two electron-donating substituents (Me and MeO) at the 3,3'-position with DIH successfully provided azaacenes **2b** and **2c** in 66% and 96% yield, respectively. The reaction using 3,3'-dibrominated BINAM **1d** gave desired product **2d** in a low yield, probably because of the poor solubility of the diamine in

t-BuOH. Notably, the rearrangement of 3,3'-diphenyl diamine **1e** also efficiently proceeded to afford **2e** in a high yield, indicating that steric hindrance around the amino moieties does not affect the reaction efficiency. In sharp contrast, diamine bearing two ester groups (CO₂Me) at the 3,3'-position did not undergo the rearrangement at all. This significant lack of reactivity might be ascribed to the low nucleophilicity of amino moieties, inhibiting the formation of N–I bonds (*vide infra*). Diamines bearing the 7,7'- and 6,6'-disubstitutent also underwent rearrangement to selectively provide **2f** and **2g** in moderate yields. Notably, the rearrangement of bianthracene diamine **1h** gave highly conjugated heptacyclic azaacene **2h**, which should be quite difficult to synthesize by conventional

Table 2 Scope and limitation of the rearrangement of 1^a

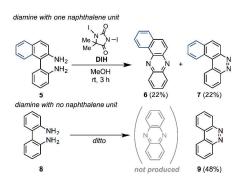

organic reactions.

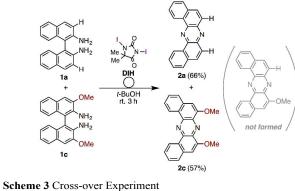

^{*a*} Reaction Conditions: **1** (0.2 mmol) and **DIH** (1.6 mmol) in *t*-BuOH (20 mL) at rt for the indicated time. ^{*b*} MeOH was used as a solvent.

Regarding mechanistic aspects, importantly, the existence of at least one naphthalene unit is indispensable for the unique rearrangement (Scheme 2): when biaryldiamines bearing one (5) and none (8) of naphthyl unit were subjected to the reaction conditions, the ratios of rearranged product/benzocinnoline product were found to be positively correlated with the number (n) of naphthalene unit. These results might indicate the involvement of dearomatization processes in the reaction pathway (vide infra), which would be more favorable with naphthalene unit than benzene unit.¹⁴ On the other hand, crossover experiment applying an equimolar mixture of 1a and 1c resulted in no production of cross-product at all (Scheme 3), and a control experiment using β -naphthylamine under the optimal conditions led to the production of [a,h]-isomer without the formation of 2a [eqn (2)], suggesting the intramolecularity of the rearrangement.

Journal Name

Scheme 2 Influence of naphthalene unit

Although precise mechanism should await further investigation, in conjunction with the accumulated knowledge on the reactivities of aromatic amines toward electrophilic iodinating oxidants, a tentative reaction pathway is illustrated in Fig. 1. The reaction would start with exchange of N-H hydrogen(s) with iodine, leading to mono or di N-iodoamine A.⁸ Dearomatization process to form azirine **B** could explain the indispensability of naphthyl unit for the rearrangement.¹⁵ Upon **B** is formed, the highly strained intermediate would be attacked by an intramolecular amino nucleophile (Ar-NH₂), and the developing anion would be trapped by extra iodinating reagent to form C.¹⁶ Nitrene D could be generated from C driven by the release of its strain energy, and the subsequent insertion of nitrene to the C(Ar)-C(Ar) bond would give phenazine 2a. Alternatively, the path from C to 2a could be interpreted as a variant of Stieglitz rearrangement.¹⁷ Carbazole 4a might be produced through [3,3]-sigmatropic rearrangement of diimine that would be formed by the protonation of 1a with generating HI, and followed by the elimination of ammonia.11

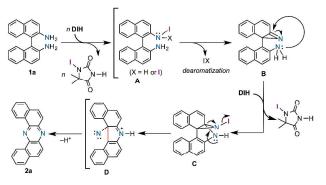

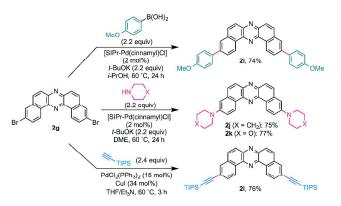

Fig. 1 A tentative pathway of the rearrangement

In light of bromo functionality of 2d and 2g, these compounds should serve as useful building blocks for functionalized azaacenes. Synthetic versatility of 2g was clearly demonstrated by the preparation of 2i-2l via Pd catalysis (Scheme 4). With slight modifications of the Nolan's original conditions,¹⁸ NHC/Pdcatalyzed cross-coupling of 2g with an arylboronic acid and cyclic amines gave the corresponding coupled products 2i-2k in good yields. Furthermore, TIPS-acetylene was efficiently cross-coupled with 2g to afford conjugation-extended azaacene 2l in 76% yield.

Scheme 4 Pd-catalyzed functionalization of 2g

Basic physicochemical properties of U-shaped azaacenes 2 were investigated. UV/Vis and fluorescence (FL) spectra as well as a cyclic voltammogram for 2a are shown in Fig. 2 as a representative example (for other compounds, see ESI[†]). The mirror-image form UV and FL spectra with fine vibrational structures and small Stokes shift (9 nm) reflect the rigid structure of 2a like typical (aza-)acenes (Fig. 2a). Likewise, diluted CH₂Cl₂ solutions of other azaacenes 2 emit fluorescence ranging from blue ($\lambda_{em} = 425$ nm) to yellow ($\lambda_{em} = 561$ nm) depending on the substituents on the conjugated core. Especially, the introduction of sterically demanding and strongly electron-donating groups like piperidino and morpholino functionalities (i.e., 2j and 2k) resulted in significant stokes shifts and greatly enhanced quantum yields (2a: $\lambda_{em} = 425 \text{ nm}$, $\Phi_f 0.14$; 2j: $\lambda_{em} = 561 \text{ nm}$, $\Phi_f 0.47$; 2k: $\lambda_{\rm em} = 543$ nm, $\Phi_{\rm f} 0.42$), probably ascribed to intramolecular charge-transfer (ICT) emission. Notably, most of azaacenes 2 showed one pair of reversible redox waves at the potentials ranging from -1.76 to -1.98 V against the Fc/Fc⁺ redox couple

as shown in Fig. 2b, indicating the good electron-accepting abilities of **2**. These values are compatible to those of n-type organic materials used for organic luminescence diodes (OLEDs) devices like diarylanthrazolines¹⁹ and Alg_{3} .²⁰

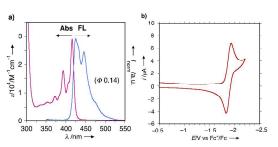

Fig. 2 a) UV/Vis absorption and FL spectra of CH_2Cl_2 solution of **2a** (10⁻⁵ M order). b) Cyclic voltammogram of CH_2Cl_2 solution of **2a** (10⁻⁴ M order) with nBu_4NPF_6 as an electrolyte.

In conclusion, we have discovered an unprecedented oxidative skeletal rearrangement of BINAMs and established an approach to constructing novel type of azaacenes that are otherwise difficult to synthesize by conventional methodologies. Investigation into the creation of functional conjugated materials based on these unique azaacenes are undergoing in our laboratory.

We deeply thank Professor Toshiyuki Moriuchi of Osaka University for his assistance of single-crystal X-ray diffraction experiments. This research was partly supported by the research Grants from Izumi Science and Technology foundation and from The Murata Science Foundation, the Sasakawa Scientific Research Grant from The Japan Science Society, and the Research Encouragement Grants from The Asahi Glass Foundation (to Y.T.).
