DOI: 10.1039/x0xx00000x

Copper (II)-catalyzed boronic acid promoted C-N bond cross-coupling reactions have been successfully developed for sequential N-arylation of C-amino-NH-azoles. These general protocols are compatible with a variety of aryl/heteroaryl boronic acids and provided rapid access to diverse array of diarylaminazole derivatives in two-steps sequence or in one-pot.

Transition-metal catalyzed N-(hetero) arylations are important synthetic tool in organic chemistry.1 Besides the traditional copper promoted Ullmann type coupling, the palladium-catalyzed reactions championed by Buchwald and Hartwig has been a major breakthrough in this area. However, the application of palladium- and copper-mediated N-arylation reactions in the synthesis of N-arylated heterocyclic compounds with medicinal properties not always straight forwards often required optimized conditions particularly with the help of expensive ligands.2 Furthermore, use of strong base and elevated temperature makes this procedure less attractive for functional group tolerability during structure activity relationship (SAR) and lead optimization study in medicinal chemistry.

Copper salt-promoting Chan-Lam type coupling reactions for the synthesis of N-aryl heterocyclic compounds have been extensively studied over the past few years.3 Reason behind popularity of this type of cross-coupling reaction is mild reaction conditions e.g. room temperature, weak base and ambient atmosphere (Open-flask chemistry).4 N-Aryl azoles are important building blocks in numerous agro chemicals, pharmaceuticals and biological active compounds. Both Pd-and Cu-catalyzed efficient methods for N-arylation of azoles have been reoprted.5,6 However, the transition metal-catalyzed N-arylation strategies have rarely been applied in selective N-arylation over other nucleophilic sites including aromatic amines of these important heterocycles (Figure 1).7 Because, the development of optimized catalytic conditions for the selective N-arylation of these heterocycles possessing multiple nucleophilic sites is much more challenging from synthetic point. Furthermore, transition metal-catalyzed N-arylations using cyclic amidines (e.g. 2-aminobenzimidazole, 3-aminindazoles, 3-aminopyrazolopyridine, 2-aminopyridimidazoles) as substrates remain always challenging, as these functionalities coordinate strongly with reactive metals.8 These limits need to be addressed with strategy that can be widely applicable.

Table 1 Sequential N-arylation of C-amino-NH-azoles

In particular we sought to explore reaction conditions for sequential N-arylation of C-amino-NH-azoles9 (bearing different nucleophilic sites). We herein, report Cu-catalyzed boronic acid promoted N-arylation of C-amino-NH-azoles to access di-aryl amino azoles (Scheme 1) sequentially. To the best of our knowledge for the first time pyrazolopyridines and pyridimidazoles like substrates bearing two different nucleophilic sites have successfully been utilized in selective N-arylation.

To find an effective catalytic system for the selective cross-coupling of C-amino-NH-azoles, our initial attempt was inspired by a method developed previously in our group for N-arylation of 2-amino-N-heterocycles.10 7-Aza derivative of 3-aminindazole (i.e.1H-pyrazol[3,4-b]pyridine-3-amine11,1a) became an interesting choice
as model substrate due to its unique N-atom position in both the rings. Our initial attempt to perform the cross-coupling reaction of 1a with phenylboronic acid (1.1 equiv) by using Cu(OAc)\(_2\) (1 equiv) in DCE at room temperature (Table 1, entry 1) was not successful. To our delight by changing the solvent to CH\(_3\)CN the \(N^1\)-arylated product (2a) isolated in 45% yield (Table 1, entry 2). When we used MeOH as solvent (Table 1, entry 3), the yield improved dramatically (80%), perhaps due to the increased solubility of the reagents. Under these conditions the \(N^1\)-arylation is completely regioselective as only \(N^1\)-aryl azole was isolated.

\(^a\) Reaction conditions: pyrazolopyridine (1.0 equiv), phenylboronic acid (1.1 equiv), Cu(OAc)\(_2\) (0.2 equiv), MeOH (2 mL), rt, air; \(^b\) isolated yield; the yield in parentheses refers to recovered starting material \(1a\); \(^c\) reaction under 1atm O\(_2\); \(^d\) reaction under N\(_2\) atmosphere; \(^e\) Et\(_3\)N (3 equiv) used, n.r. = no reaction.

Encouraged by this promising result, we used catalytic amount of Cu(OAc)\(_2\) (0.2 equiv) and the \(N^1\)-arylated product (2a) was isolated in 90% yield (Table 1, entry 4). Further screening showed that solvents like DMF (Table 1, entry 5), DMSO (Table 1, entry 6) were not effective, while DME (Table 1, entry 7) failed to promote the reaction. We observed a sharp decline in yield when we replaced of Cu(OAc)\(_2\) with Cu(OI\(_2\)) (Table 1, entry 8). Other Cu-salts e.g. Cul (Table 1, entry 9) and Cu\(_2\)O (Table 1, entry 10) failed to give any cross-coupled product. Reaction under 1atm O\(_2\) did not show any further improvement in the yield of the reaction (Table 1 entry 11) while incomplete conversion and poor yields were observed under N\(_2\) atmosphere (Table 1 entry 12) suggesting that O\(_2\) (air) plays a vital role in the catalytic cycle. Under standard Chan-Lam conditions (Table 1 entry 13) mixture of products were formed and the isolated yield of \(N^1\)-arylated product (2a) is only 20%.

Under the optimized reaction conditions, first we examined the scope of the boronic acids with 1H-pyrazolo[3,4-b]pyridine-3-amine\(^{12}\) (Table 2). 1H-pyrazolo[3,4-b] pyridine-3-amine underwent the reaction with different boronic acids to give the desired \(N^1\)-arylated products (2a-h) in excellent yields (80-90%). Boronic acids bearing both electron-donating (2b) and electron-withdrawing groups (2c-h) underwent the reaction smoothly and no other isomer or poly arylated product was formed. We have investigated two bicyclic boronic acids, in the case of 2-naphthylboronic acid the yield is 80% (2i) whereas benzo[d][1,3]dioxol-5-ylboronic acid resulted in 85% (2j) yield. Further scope of this reaction tested with other heterocyclic boronic acids and to our expectation the \(N^1\)-arylated products (2k-o) were isolated in high yields. The only noticeable point, in case of 3-pyridylboronic acid (2i) is the prolonged reaction time (24 h) with diminished yield (60%). A further evaluation of the scope of this methodology revealed that the reaction also proceeded smoothly with other C-amin-NH-azoles e.g. 3-aminoindazole and 3-aminopyrazole, providing access to \(N^1\)-aryl indazole (2p) and \(N^1\)-aryl pyrazoles (2q-r) in excellent yields (72-88%).

Next we focus our attention on selective \(N^1\)-arylation of another two important heterocycle 2-aminobenzimidazole\(^{13}\) and 2-amino pyridopyrimidazolone\(^{14}\) (3H-imidazo[4,5-b]pyridin-2-amines). Synthetic challenges are associated with selective \(N\)-arylation of unprotected 2-aminobenzimidazolone or 2-amino pyridopyrimidazolone as the formation of regioisomer and/or poly arylated products due to tautomeric nature of these heterocycles. To our delight under the optimized conditions various boronic acids coupled with 2-aminobenzimidazolone to give \(N^1\)-selective arylated products (3a-g, Table 3). Under these optimized conditions \(N^2\)-arylated/polyarylated (C-NH\(_2\)) products were not detected. Here also the electronic nature of the boronic acids did not play any significant role in the isolated yields (82-92%). In this context heteroaryl boronic acid also examined, in case of 3-pyridyl boronic acid the isolated yield is 75% (3h) in 24 h. To further enhance the substrate scope substituted 2-aminobenzimidazoles were investigated both 5-bromo and 5-nitro derivatives reacted with 3-chlorophenyl boronic acid to give \(N^1\)-arylated products in 82% (3l) and 80% (3m) yield respectively. Interestingly, both bromo and NO\(_2\) functionalities were
tolerated under these conditions, amenable to further functional group transformations. In recent days imidazo[4,5-b]pyridine heterocycle, a versatile purine isostere and important ring system found in medicinal chemistry application of potential therapeutic benefits. Thus selective functionalization of this heterocycle will be interesting from drug discovery point. To the best of our knowledge selective N-arylation of imidazopyridine is unexplored. With our optimized conditions we subjected 2-aminopyridoimidazole with different boronic acids and to our delight the N-arylation occurred selectively to give only N'-arylated product (3k-m) in excellent yields (72-78%). Notable, no N'-arylated/poly-arylated \((C-NH_2)\) products were detected under these optimized conditions.

\(^\text{a}\) Reaction conditions: \(2\)-aminobenzimidazole (1 equiv), boronic acid (1.1 equiv), Cu(OAc)\(_2\) (0.2 equiv), MeOH (2 mL), rt, air, 12-24 h.

After successful optimization of regioselective N'-arylation, we focused on exploring conditions for second N-arylation at C-NH\(_2\) position of C-amino-NH-azoles. Our initial attempt started with the reaction of 1-(3-chlorophenyl)-1H-pyrazolo[3,4-b]pyridin-3-amine \((2f)\) and phenylboronic acid under Chan-Lam conditions and the reaction was unsuccessful (Table 4, entry 1). Then we used the inorganic base K\(_2\)PO\(_4\) (1.5 equiv) and DMF as the solvent at 100 °C by the use of Cu(OAc)\(_2\) (0.2 equiv) as the catalyst. To our delight, the reaction afforded N-arylated heterocycle, 4a in 35% yield (Table 4, entry 2). It was found that employing CsOPiv\(_3\) \((0.4 \text{ equiv})\) as the base showed the best activity \((87\%)\). Table 4, entry 11) at 50 °C, while other bases such as Cs\(_2\)CO\(_3\), K\(_3\)CO\(_3\), Na\(_2\)CO\(_3\), NaOAc, tBuOK and NaOPiv were less effective (Table 4, entries 3-8). We attempted different reaction temperatures, and 50 °C was found optimal (Table 4, entries 10-11). Screening of different solvents also was not effective in improving the further yield (Table 4, entries 12-14). A lower yield was obtained when employing Cu(OTf)\(_2\) as a catalyst (Table 4, entry 15). Under the nitrogen atmosphere, only a small amount of 4a was obtained (Table 4, entry 16).

With the optimized reaction conditions first we explored the scope of this method with 1-aryl-1H-pyrazolo[3,4-b]pyridin-3-amine. To our delight, all the electronically diverse boronic acids underwent clean conversion (Table 5) to give desired C-NH\(_2\)-arylated products \((4a-e)\) in excellent yields (78-86%). In this aspect other C-amino-N-aryl-azoles systems were also tested and the resulted C-NH\(_2\)-arylated products \((4f-h)\) isolated in good yields (70-76%).

\(^\text{a}\) Reaction conditions: N'-aryl-C-NH\(_2\)-azoles (1 equiv), boronic acid (1.2 equiv), Cu(OAc)\(_2\) (0.2 equiv), CsOPiv (0.4 equiv), DMF (1 mL), 50 °C, air, 16-20 h.

Several mechanistic studies have been reported for Chan–Lam type of coupling reactions.\(^{15,9b}\) The coupling product \([\text{Ar–azole}(\text{Nu})]\) could be generated by reductive elimination from a copper (III) intermediate \([\text{Ar–Cu(III–Nu)}].\(^{24}\) The presence of \(O_2(\text{air})\) here favors this step by \textit{in situ} oxidation of the corresponding \([\text{Ar–Cu(II–Nu)}]\) complex.\(^{15b,4d,e}\) Finally, \(O_2(\text{air})\) acts as a terminal oxidant to regenerate the catalytically active species after the reductive elimination step.\(^{10,15b}\)
In summary, we have developed two simple and inexpensive systems for copper-catalyzed sequential $N$-arylations of C-amino-NH-azoles with aryl/heteroaryl boronic acids. Undoubtedly, the success of these sequential/one-pot Cu-catalyzed C-N bond formation reactions further extend the usefulness of Chan-Lam type of coupling with new substrate class.

D.N.R and Sk. R. thanks UGC and CSIR-New Delhi for research fellowship, respectively. This research work financially supported by CSIR-NewDelhi (BSC 0108). IIIM communication No 1674.
