This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
A novel zwitterionic near-infrared (NIR) dye, ZWCC, has been designed and synthesized. It shows significantly enhanced photostability and chemical stability compared to the existing zwitterionic NIR dye. In addition, the feasibility of labeling ZWCC with biological ligands was investigated and used in live cell imaging applications.

Near-infrared (NIR) fluorophores have attracted substantial attention in various chemical and biological studies due to their great advantages for in vivo imaging. Firstly, NIR wavelengths ranging from 700 nm to 900 nm can penetrate into deeper tissues. Secondly, the low auto-fluorescence background of NIR fluorophores is essential for in vivo images. In view of rising interests in small animal optical in vivo imaging, there have been high demands for the design and synthesis of novel NIR fluorophore with better photophysical properties and chemical properties.

Till now, the famous and extensively used NIR fluorophore dye, indocyanine green (ICG), has good clinical availability and safety properties. However, its low fluorescence quantum yield, short fluorescence lifetime, poor photostability, bad chemical stability, as well as the lack of reaction sites to target ligands have hindered its application in chemical and life sciences. One recently developed zwitterionic NIR fluorophore ZW800-I shows improved in vitro and in vivo performance. In brief, the NIR fluorescent small molecule ZW800-I can be rapidly cleared by kidneys, thereby exhibiting low background fluorescence due to less non-specific binding to normal tissues and organs. Moreover, ZW800-I contains one carboxylic acid group, which can be modified by functional groups for covalent conjugation to target ligands through a stable amide bond. However, every coin has two sides, the additional carboxylic acid, which is the reactive site for targeting ligands, was introduced by replacing chloro of meso-chloro cyclohexenyl moiety with alkoxy group via ether linkage formation. Consequently, this molecular assembly becomes chemically less stable. When there is a strong nucleophilic group present, the reactive site containing ether linkage in cyanine dyes may undergo nucleophilic substitution at the oxygen position via a S_N1 mechanistic pathway. Therefore, the possibility of using the ZW800-I dye in a harsh environment becomes limited.

Previously, Lee et al. reported the palladium-catalyzed C-C coupling reactions of chloro-substituted carbocyanines. Inspired by this approach, we designed and synthesized a novel zwitterionic near-infrared fluorophore which contains a C-C cross-coupling reaction of hydrophilic chloro-substituted heptamethine cyanines with arylboronic acids. The new NIR zwitterionic C-C bond formed cross-coupling product, which we named as ZWCC, is not only devoid of chemically vulnerable ether linkage, but also has improved photostable characteristics. Here, we present the design and systematic study of the spectroscopic properties of this novel zwitterionic NIR fluorophore (Scheme 1). Its photostability and chemical stability, as well as its application in live cell imaging are evaluated.

Spectra properties of the newly synthesized dye ZWCC were first tested in DMSO and compared with those of ICG and ZW800-I (Fig. 1 and Table 1). The absorption spectra of these three dyes show a characteristic band in the range of 780-800 nm, while, the fluorescent spectra of the three compounds show some difference in emission wavelength and fluorescence intensity. Based on the same concentration, both ZW800-I and ZWCC show stronger fluorescence intensity compared to ICG. This is a good achievement since fluorescence intensity plays an important role in practical applications, especially in in vivo imaging, where higher fluorescence intensity can significantly lower the detection limit.

To further analyze and compare ZWCC with ICG, we characterized the absorption and emission spectra of these two dyes in different solvent system, such as DMSO, PBS, H_2O and MeOH. The data was summarized in Fig. S1 and Table S1. The absorption spectra of ICG show significant absorption peak around 780 nm in all solvent systems and significant aggregation in H_2O. For ZWCC, the absorption spectra are closely matched in PBS and H_2O, with a clear new absorption peak at 680 nm. However, the absorption
spectrum in DMSO shows a single peak with significant bathochromic shift, as compared to that measured in PBS.

Fluorescence quantum yields were determined using ICG (Φ=0.13 in DMSO) as a standard. Stoked shifts of ICG, ZW800-1 and ZWCC.

The aggregation tendency of ZWCC is evident from its absorption spectra taken in H₂O and PBS. From the area-normalized absorption spectra (equaling the concentration-weighted absorbances for different dye concentrations) shown in Fig. S2, we can see that ZWCC aggregates in H₂O even at concentration as low as 0.5 μM. And increasing the concentrations of ZWCC will lead to the typical blue shift in absorption, which indicate that ZWCC forms the frequently observed H-type aggregation as displayed by the vast majority of cyanine-type fluorescent dyes. The formation of non-fluorescent H-type aggregation is supported by the excitation spectra in different solvent (Fig. S3). Even the absorption spectra of ZWCC in PBS, H₂O and MeOH show clear blue-shifted absorption bands, all the excitation spectra are similar to the excitation spectra in DMSO, in which ZWCC does not show aggregation signal.

Quantum yield (Φ) is also a key parameter to evaluate the practical application of dyes. Table S1 compared the quantum yield of ZWCC and ICG, where it shows that the quantum yields of ZWCC in relatively different solvents are much larger than the values of ICG due to the good solubility of ZWCC in aqueous phase, which will further benefit its biological applications.

A comparative analysis for the photostability of ICG, ZW800-1 and ZWCC dyes was carried out by performing the time-course fluorescence measurements in PBS buffer. First, fluorescence intensities of these dyes are examined under a strong UV lamp (UVP Blak-Ray1B-100AP high intensity mercury lamp, 100 W, 365 nm). By exposing these three compounds to a strong UV lamp and monitoring their fluorescence intensities, we observed that the average fluorescence intensity decrease for ICG and ZW800-1 were around 85% and 30% due to decomposition, respectively, whereas the newly designed ZWCC did not show any observed decrease after 1 h irradiation (Fig. 2).

Based on the comparison, it can be concluded that ZWCC exhibited a remarkably higher photostability than ICG and ZW800-1. We hypothesize that the incorporation of a rigid cyclohexenyl ring in the polymethine chain increases the dye’s photostability compared to cyanine dyes with an open polymethine chain. In addition, the robust C-C bond also plays an important role for enhancing the photostability of ZWCC.

![Fig. 2](image) Photostability evaluation of ICG, ZW800-1 and ZWCC derivatives under strong UV irradiation. Compounds were dissolved in PBS buffer (pH 7.4) containing 1% DMSO to a 10 μM final concentration, and fluorescence measurements were recorded for 1 h at rt. Values are represented as means for sequential measurement every 10 min and fitted to a non-linear regression, one-phase exponential decay.

Besides the photostability of NIR dyes, chemical stability is also an important factor when considering further chemical modification with functional groups. First, we tested the stability of ZWCC under certain biological environments, like pH5 and pH10, and the results showed that ZWCC is stable even after 20 h incubation (Fig. S4). Both ZW800-1 and ZWCC provide one carboxylic acid for further modification. We evaluated the chemical stability of ZW800-1 and ZWCC by examining the nucleophilic reaction between the dyes and primary amine (Fig. S5). The HPLC-MS results show that under the same reaction condition, amide bond formation product was clearly certified for ZWCC with high conversion yield. On the contrary, for ZW800-1, only byproduct (central oxygen position replaced with amine) formation was observed (Fig. S6). These results demonstrate that the robust C-C bond provides an easier approach for modification at the single carboxylic acid linker position, leading to the superior chemical stability of ZWCC even under harsh environment.

Signal-to-noise (S/N) ratio is a significant criterion for bioimaging. To evaluate the S/N ratio of ZWCC, ZWCC was injected to BALB/c nude mouse and the animal was imaged. It is clear from the images that ZWCC was distributed to organs including liver, pancreas, kidneys, spleen, intestine and fat pad. Subsequently, the signal quickly disappeared from the liver, pancreas, spleen, intestine and fat pad. Within 1 h, fluorescence signal has mostly cleared from the whole body and only very weak
signal remained to be observed in the kidneys and bladder, which indicated the low background of ZWCC (Fig. S7).

To further demonstrate the feasibility of labeling biological ligands, we conjugated the new zwitterionic NIR fluorophore ZWCC to a cyclic peptide consisting of cyclo (RGDyK) (cRGD), which shows specifically binding to integrin αvβ3. Integrins are expressed on a wide variety of cells to mediate cell-extracellular matrix interactions and the integrin receptor, αvβ3, in particular is an angiogenic marker expressed in most regions of tumors.23 Several potent small molecules containing the arginine-glycine-aspartate (RGD) sequence have been found to block integrin function and inhibit tumor angiogenesis.24 These promising results have suggested that integrin receptors are important targets for drug delivery and therapy, as well as molecular imaging.

We synthesized two cRGD-conjugated ZWCC compounds as possible probes for monitoring tumor angiogenesis. We evaluated integrin-targeting and cellular uptake of cRGD-conjugated ZWCC compounds by fluorescence imaging analysis using αvβ3 integrin-positive U87MG cells and αvβ3 integrin-negative MCF7 cells. As shown in Fig. 3, both ZWCC-C6-cRGD and ZWCC-PEG4-cRGD were internalized by U87MG cells during the incubation period. As a negative control, incubating all three integrin-targeted ZWCC compounds did not yield any signals in αvβ3 integrin-negative MCF7 cells. Similarly, no signal was observed when cells were treated with ZWCC alone (data not shown). In addition, the fluorescent signal from ZWCC-linker-cRGD could be effectively inhibited when U87MG cells were pre-treated with free cRGD peptide, indicating the specificity of ZWCC-linker-cRGD binding to integrin αvβ3 (Fig. S8).

In summary, we have developed a novel zwitterionic NIR dye, ZWCC, which shows significantly enhanced photostability as well as chemically stable properties. Also, based on their functional carboxylic acid group, we designed and constructed two cRGD-modified NIR probes which demonstrated specific integrin-targeting in live cells. Taken together, we anticipate that the newly developed zwitterionic NIR dye, ZWCC, will offer a better and improved option in the field of NIR imaging.
