This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
A novel approach for the synthesis of tertiary propargylamines is achieved through a Cu(OAc)$_2$-catalyzed multicomponent reaction of primary amines, formaldehyde, arylboronic acids and alkynes, where a combination of PBM and A$^3$-coupling reactions is involved in this new multicomponent reaction.

Multicomponent reactions (MCR), generally with high selectivity, flexibility and atom economy, are one of the most powerful synthetic strategies to access diverse complex structures from small molecular compounds.$^1$ And a variety of new MCRs have been developed.$^2-5$ Among them, the combination of MCR (MCR$^2$), which combines two different types of MCRs in a single process, has gained considerable attentions.$^6$ However, the Ugi reaction, as well as isonitriles are indispensably involved in most of MCR$^2$ cases.$^2,5,c-4$ Therefore, the development of novel MCR$^2$ without Ugi reaction is highly valuable.

The three-component reaction of aldehydes, amines and alkynes (A$^3$-coupling) provides an efficient strategy to the synthesis of propargylamines, which are often useful key intermediates and building blocks for the preparation of many biologically active compounds.$^5,a$ A number of metal catalysts, such as Au salts,$^7,a$ Ag salts,$^7,c$ FeCl$_3$/Fe$_3$O$_4$/Fe$_3$O$_7$,$^7,c-d$ InCl$_3$,$^7,e$ Cu salts,$^7,f-7$i and so on,$^7,a,b$ have been applied for this reaction via C-H activation of terminal alkynes. Meanwhile, the Petasis-borono Mannich (PBM) reaction of aldehydes, amines and boronic acids, developed by Petasis in 1993,$^1$ has attracted considerable attention in the synthesis of diverse α-hydroxyl amines, α-amino acids and nitrogen-containing heterocycles.$^9,10$ Realizing both amines and aldehydes are involved in A$^3$-coupling and PBM reactions, and a second amine is generally preferable to primary one in A$^3$ reaction,$^5,a$ it is possible to develop a novel multicomponent reaction in which the secondary amines produced from PBM reaction could serve as the amine component in further A$^3$-coupling to construct the final propargylamines. Thus, a novel five-component MCR$^2$ of PBM and A$^3$-coupling reactions has been accomplished and reported herein (Scheme 1).

At the outset, CuI was chosen as the catalyst to screen the effect of solvents on the model reaction of aniline, formaldehyde, phenylboronic acid and phenylacetylene at 80 °C for 24 h. The nature of solvent significantly affected the reaction (Table 1). Among the solvents screened, 1,2-dichloroethane (DCE) was found to be the most suitable solvent for this combination of PBM and A$^3$-coupling reactions with a desired product yield of 86% (Table 1, entry 1). Toluene was inferior and generated the corresponding product in 72% yield (Table 1, entry 2), whereas acetonitrile and 1,4-dioxane afforded lower yields of the desired products (Table 1, entries 3-4). Tetrahydrofuran (THF), ethanol and water delivered less than 5% yield (Table 1, entries 5-7), and no desired product was determined when the reactions were performed in N,N-dimethylformamide (DMF) and dimethyl sulfoxide (DMSO) (Table 1, entries 8-9). When the reaction was performed in the absence of solvent, a lower yield of 22% was obtained (Table 1, entry10). And no desired product was detected without the catalyst (Table 1, entry11).
We next investigated the catalytic activity of various copper salts (Table 2). Cu(OAc)₂ was found to be the most effective catalyst with a high yield of 96% (Table 2, entry 6). Interestingly, except for Cu(OAc)₂, Cu(I) catalysts showed better catalytic activities than Cu(II) catalysts (Table 2, entries 1-12). Cu(OAc)₂ was therefore adopted for the optimization of other reaction conditions. As to the temperature, 80 °C was found to be optimal. The reactions at lower temperatures generated less product (Table 2, entry 13-14). Lowering the catalyst loading amount to 5 mol %, or reducing the reaction time to 12 h also resulted in a decrease of yield (Table 2, entries 15-16).

On the basis of the optimized reaction conditions (Table 2, entry 6), the scope of this five-component reaction was evaluated (Table 3). In general, for all components in this reaction, electron-donating substituents (-MeO and -Me) on the phenyl ring lead to higher yields than electron-withdrawing groups (-Cl and -F) (Table 3, entries 1-7, 13-17 and 19-23). The reaction was almost ceased when a reactant with highly electron deficient substituent, such as 4-nitroaniline or 4-(trifluoromethyl)phenylboronic acid was adopted (Table 3, entries 8 and 18). For the amine component, substituted anilines delivered corresponding products in 60-92% yields (Table 3, entries 1-7). Aliphatic amines, such as phenylmethanamine and butan-1-amine, also delivered desired products in satisfactory yields (Table 3, entries 9-10). Furthermore, the successful application of methyl 2-aminocetate and methyl 2-aminopropanoate in this MCR\(^\text{2}\) (Table 3, entries 11-12) might provide a complementary approach to the functionalization of NH-terminal amino acid esters or peptides.}\(^\text{7,8}\) As for the alkyne component, in addition to the success of phenylacetylenes (Table 3, entries 1-7, 9-17 and 19-23), aliphatic alkynes also worked smoothly and desired products were obtained in moderate yields with prolonged reaction time of 48 h (Table 3, entries 24-26).
A tentative mechanism for this five-component reaction is proposed in Scheme 2. The reaction of primary amine 1, formaldehyde 2, and arylboronic acid 3 afforded a secondary amine 6 via PBM reaction, which was detected by GC-MS throughout the reaction. The secondary amine 6 might further react with formaldehyde 2 to produce iminium intermediate B. The copper acetylide intermediate, generated from alkyne 4 and Cu(OAc)$_2$, reacted with iminium B to give the corresponding propargylamine 5 and regenerated the copper catalyst for further reactions.$^{7,7}$ Thus, this five-component reaction involved a MCR$^2$ of PBM and A$^1$-coupling reactions.

In conclusion, we have developed a novel approach to the synthesis of tertiary propargylamines via a rationally designed Cu-catalyzed multicomponent reaction of primary amines, formaldehyde, arylboronic acids and alkenes. The combination of PBM and A$^1$-coupling reactions provides an efficient and fast one-pot approach to the tertiary propargylamines. Both aromatic and aliphatic amines and alkenes are applicable. Furthermore, the MCR$^2$ also provided a complementary pathway to the functionalization of NH$_2$-terminal amino acid esters and peptides.
