This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Ultrasound assisted-cloud point extraction combined with flame atomic absorption spectrometry for selective preconcentration and determination of As(V) in selected water and beverage samples

Abstract

In present study, to evaluate the inorganic arsenic species at µg L⁻¹ levels, a simple, low-cost analytical method has been developed using flame atomic absorption spectrometry (FAAS). The ultrasound-assisted cloud point extraction (UA-CPE) was efficiently used to separate and preconcentrate As(V) in presence of excess As(III) in different samples of water and beverages. The selective ion-association complex and/or π-stacking complex of As(V) with 3-amino-7-dimethylamino-2-methylphenazine (Neutral red, NRH⁺ or NR) in presence of Pyrogallol at pH 8.0 were extracted into the surfactant-rich phase of polyethyleneglycolmonononylphenylether (PONPE 7.5) from the sample matrix. After optimization of the UA-CPE conditions, the limits of detection and quantification (LOD and LOQ) obtained for As(V) with sensitivity enhancement factor of 47.3 at the linear range of 1.5-170 µg L⁻¹ were 0.45 and 1.5 µg L⁻¹, respectively. The relative standard deviation (RSD) as a measure of precision was found in range of 2.7-4.2 %. The proposed method was successfully applied to the determination of As(V) and total As in selected water and beverage samples after rapid and efficient ultrasonic- and microwave-assisted extraction approaches before and after pre-oxidation with KMnO₄ in acidic media. The concentration of As(III) was calculated from difference between total As and As(V) concentrations. The accuracy was validated by analysis of two certified standard reference materials (SRMs) including recovery rates of spiked samples.

Keywords: Inorganic Arsenic Species, Neutral Red, Ultrasound-Assisted Cloud Point Extraction, Waters, Beverages, Flame Atomic Absorption Spectrometry
Highlights

• A new UA-CPE method was efficiently combined with FAAS for selective detection of As(V).
• The method is based on the ion-association of As(V) with NRH⁺ in presence of Pyrogallol.
• A detection limit of 0.45 µg L⁻¹ for As(V) at the linear range of 1.5–170 µg L⁻¹ was achieved.
• It is a selective and sensitive method for monitoring of trace As(V).
1. Introduction

Arsenic (As) is one of the most toxic elements that occurs in both inorganic and organic forms. Both forms of As can be found in the environment from natural sources and anthropogenic activities. Arsenic has received increased attention in recent years because of its carcinogenic and other toxic properties such as dermal changes, pulmonary, cardiovascular, gastrointestinal, hematological, renal, neurological, reproductive, immunologic and genotoxic, mutagenic. Speciation of inorganic arsenic in terms of As(III) and As(V) is often as important as total As quantification because of its varying degrees of toxicity. Arsenic in food and beverages has recently drawn the attention of analytical chemistry. Conventional atomic and molecular spectrometric methods typically measure total arsenic and are unable to differentiate the different arsenic species. Because different arsenic species have greatly different toxicities, inorganic arsenic is more toxic as compared to organic arsenic. Thus, new analytical methods are simultaneously needed to separate and quantify the inorganic arsenic species, As(III), As(V) and total As in order to assess the risks on human health related to the presence of arsenic in beverage and foods.

In general, the widely used analytical techniques for the direct detection of the arsenic species in water and beverage samples are high performance liquid chromatography coupled to inductively coupled plasma mass spectrometry (HPLC–ICP-MS), inductively coupled plasma optical emission spectrometry (ICP-OES), hydride generation-atomic fluorescence spectroscopy (HG-AFS), hydride generation atomic absorption spectrometry (HG-AAS), flame atomic absorption spectrometry (FAAS), inductively coupled plasma mass spectrometry (ICP-MS), graphite furnace atomic absorption spectrometry (GF-AAS), and electrothermal atomic-absorption spectrometry (ET-AAS) until now. Among these techniques, FAAS is still widely used in analytical chemistry. Moreover, the device has advantages such as convenience, selectivity, speed, precision and accuracy than others. Because of matrix effect and being at trace levels of arsenic in water and beverage samples, separation and preconcentration steps are still necessary for especially FAAS method with low sensitivity. Thus, preliminary separation and preconcentration are required prior to FAAS determination. For the determination of As(III) and As(V), the separation and preconcentration methods reported in the literature are usually based on atomic spectroscopic
techniques after solid phase extraction (SPE),\textsuperscript{19} dispersive liquid–liquid microextraction (DLLME),\textsuperscript{20} single-drop microextraction (SDME),\textsuperscript{21} liquid–liquid extraction (LLE),\textsuperscript{22} coprecipitation\textsuperscript{23} and ultrasound assisted emulsification of solidified floating organic drop microextraction (USA-E-SFODME).\textsuperscript{24} But these procedure have drawbacks such as time-consuming, unsatisfactory enrichment factors, using toxic organic solvents and forming secondary wastes. Unlike them, Cloud point extraction (CPE)\textsuperscript{14} is a versatile method for the separation and preconcentration of metal ions having considerable properties such as simplicity, inexpensive compared to organic solvents, fast, selectivity and sensitivity.

The main aim of the present work was to develop a rapid, sensitive, selective, accurate and reliable method for separation and preconcentration of only one specie, As(V) or As(III), of inorganic As species in water and beverage samples using ultrasonic assisted (UA)-CPE technique prior to FAAS. The method is based on the selective ion-association of As(V) with 3-amino-7-dimethylamino-2-methylphenazine (Neutral red, NRH\textsuperscript{+} or NR) in presence of Pyrogallol at pH 8.0, and then extraction of ternary complex to micellar phase of polyethyleneglycolmono-p-nonylphenylether (PONPE 7.5) as extracting agent. The factors influencing the efficiency of UA-CPE for accelerating ion-association reaction and facilitating phase separation were systematically investigated. The method was applied successfully to the determination of As(III), As(V) and total As after selective separation and preconcentration of trace As(V) in water and beverage samples with UA-CPE.

2. Experimental

2.1. Instrumentation

An atomic absorption spectrometer (AAS-6300, Shimadzu, Kyoto, Japan), equipped with D\textsubscript{2}-background correction, arsenic hollow cathode lamp and an air-acetylene flame atomizer, was used for arsenic determinations. The wavelength, lamp current and spectral bandwidth were 197.2 nm, 10 mA, 0.2 nm, respectively. A centrifuge (Universal-320, Hettich Centrifuges, and England) was used to accelerate the phase separation process. The pH measurements were carried out with a pH meter (pH-2005, JP Selecta, Spain). Eppendorf vary-pipettes (10–100 and 200–1000 µL) were used to deliver accurate volumes. An ultrasonic power (UCS-10 model, Jeio Tech, Co., Ltd., Seoul, Korea) was used to degas and extract the water and beverage samples, also used to maintain the temperature in UA-CPE experiments. A refrigerator at 4 °C was used to keep the samples fresh, and cool till the analysis.
2.2. Chemicals and Reagents

All chemicals and reagents used were of analytical-reagent grade or higher purity. Ultra-pure water with a resistivity of 18.2 MΩ cm was prepared using a Labconco (USA) water purification system. All solutions were prepared with this ultra-pure water. Stock solutions of As(III) and As(V) (1000 µg mL\(^{-1}\)) were prepared by dissolving appropriate amounts of As\(_2\)O\(_3\) and Na\(_2\)HAsO\(_4\) (Merck, Darmstadt, Germany) in 1 mol L\(^{-1}\)NaOH and 3 mol L\(^{-1}\)HCl solution, and then adjusting the pH to 7.0 with the water, respectively. The standard solutions used for construction of calibration curves were prepared by dilution of the stock solution with the water just before use. Stock solutions of 1.0×10\(^{-3}\) mol L\(^{-1}\) NRH\(^+\) (Sigma, St. Louis, MO, USA) were prepared fresh daily by dissolving the reagents in ethanol (Merck) and diluting with the water. As it is not possible to obtain a real aqueous solution of the nonionic surfactant, PONPE 7.5 due to low cloud point, it was practically convenient to prepare a stock solution as follows: 2.5 mL of PONPE 7.5 (Sigma) and 5 mL of ethanol were mixed and made up to 100 mL with water. For the preparation of 100 ml pH 8.0 borate buffer solution, 50 mL of 0.05 mol L\(^{-1}\) trisodiumtetraborate (Merck) and 44 mL of 0.1 mol L\(^{-1}\)HCl (Merck) solutions were mixed. The Pyrogallol solution, 1.0×10\(^{-3}\) mol L\(^{-1}\) were prepared by dissolving an appropriate amount of chemicals (Sigma) in the water. The vessels and pipettes used for trace analysis were kept in 10% (w/v) HNO\(_3\) for at least 24 h and subsequently washed five times with the water.

2.3. Preparation of water and beverage samples to analysis

All of the water and beverage samples selected for analysis were supplied from local supermarket in Sivas, Turkey. For the present study, four water samples, two non-alcoholic and three alcoholic beverages of different brands were randomly selected. Before preconcentration procedure, all water samples were pre-filtered using a 0.45 µm membrane filter. Initially, they were passed through a micro-column filled with a cation-exchange resin (Chelex 100 chelating resin, which is a styrene divinylbenzene copolymer that contains paired imino-diacetate, functional groups) around pH 6.0 in order to remove interfering ions like Cu(II), Fe(III), Mn(II), Ca(II) and Mg(II), which can be available at trace, minor and/or major levels in water and beverages. Thus, the effects of the possible interfering ions were greatly reduced in determination of inorganic As species. Then, the water samples were stored at 4 °C until analyzed. 50 mL of the water samples were preconcentrated by evaporation approximately to final volume of 10 mL. After that, the preconcentrated water samples for As(V) and total As were submitted to UA-CPE procedure, and analyzed by standard addition
method before and after pre-oxidation for speciation analysis in order to control the matrix effect. The As(III) contents were calculated from differences between the contents of As(V) and total As.

All beverage samples were subjected to total matrix digestion prior to analysis. Two different extraction methods are applied for the all samples. In the first extraction procedure for beverage samples, a mixture of 2.0 mol L\(^{-1}\) HNO\(_3\) and 1.5 mol L\(^{-1}\) H\(_2\)O\(_2\) (v/v, 5:1) were added to 25 mL of beverage samples into beaker of 150 mL. Then, the samples were submitted to the microwave oven programs of 5 min at 250 W, 5 min at 450 W and finally 5 min at 650 W. After extraction under microwave power, samples were cooled, transferred and diluted to calibrated flasks of 50 mL with water after filtration with a membrane filter of 0.45 µm for subsequent analysis. It is worth underlining that beverages should be diluted as little as possible to avoid diluting the low arsenic content. For oxidation of As(III) to As(V) in the extracted samples, 1.5×10\(^{-4}\) mol L\(^{-1}\) of KMnO\(_4\) solution containing 0.25 mol L\(^{-1}\) HCl was added to each, and in a similar way, the samples were submitted to the microwave oven programs of 2 min at 250 W, 5 min at 450 W, 2 min at 650 W and finally 3 min at 900 W. After oxidation with KMnO\(_4\) in acidic media, total As analysis was also made by using FAAS after preconcentration with UA-CPE under the optimized conditions.

The steps of the second extraction (ultrasonic power) process are as follows; (1) 25 mL of the beverage samples was transferred into beaker of 100 mL. (2) Then, the samples were added 10 mL of diluted HNO\(_3\) (2.0 mol L\(^{-1}\)) and 5.0 mL of diluted HClO\(_4\) (1.5 mol L\(^{-1}\)). (3) The final volume of the mixture was completed to 100 mL with ultra-pure water. (4) The mixture was initially heated in an ultrasonic bath at 65 °C for 15 min (300 watt, 60 Hz). (5) The pH of the digested samples was adjusted to 7.0 by using diluted NaOH (2 mol L\(^{-1}\)). (6) After centrifugation at 4000 rpm for 5 min, the extracted samples were filtered using the membrane filter into a volumetric flask before analysis. Similarly, the preconcentrated beverages for As(V) and total As were submitted to UA-CPE procedure, and analyzed by standard addition method before and after pre-oxidation for speciation analysis in order to control the possible matrix effect. The As(III) contents were calculated from differences between the contents of As(V) and total As. Also, two different SRMs were studied in order to verify the accuracy and precision of the method. The selected certified samples are SRM 1575a pine needles and SRM-1643e trace elements in water. The certified reference values are available for arsenic for assessment of the method accuracy. The solid reference material (0.5 g) was initially submitted to the extraction process under ultrasonic and microwave
powers. Due to contain its interfering cationic ions at high levels, in a similar way to those of water samples, it was separated from them by passing through a chelating cation-exchange resin prior to UA-CPE. The liquid reference material was not submitted to any digestion process. It was directly analyzed with the proposed UA-CPE method.

2.4. The general UA-CPE procedure

In a set of 50 mL volumetric tubes containing 2.2 mL of pH 8.0 borate buffer, 1.75 mL of $1.0 \times 10^{-3}$ mol L$^{-1}$ Pyrogallol, 1.25 mL of $1.0 \times 10^{-3}$ mol L$^{-1}$ NRH$^+$, 0.75 mL of 0.01 mol L$^{-1}$ Na$_2$SO$_4$ and 0.8 mL of 2.5% (v/v) PONPE 7.5 in the range of 1.5–170 µg L$^{-1}$ As (V) were mixed and kept in a ultrasonic bath (300 watt, 40 Hz). Ultrasound was applied to assist and accelerate CPE under the equilibrium temperature of 35 °C for 5 min to start the process of extraction and preconcentration of As(V) in the surfactant-rich phase, which accomplished in an ultrasonic cleaner. The phase separation was accelerated by centrifuging at 4000 rpm for 5 min. Then, the resulting mixtures were cooled in an ice-bath for 5 min to increase the viscosity of the surfactant-rich phase and make easy the extracted of the aqueous phase. Then, the aqueous phase was easily separated from surfactant-rich phase by inverting the tube. The surfactant-rich phase was dissolved and diluted to 1.0 mL of methanol containing 1.0 mol L$^{-1}$ HNO$_3$, and then the resultant solution was directly introduced into FAAS for determination of As(V) as analyte. Finally, the inorganic As contents of water, beverage and certified samples were determined by using standard addition method in order to control the possible matrix effect around the detection limit.

2.5. Speciation study

In the sense of method development, Neutral red as ion-pairing reagent is a cationic phenazine group dye with a pK$_a$ value of 6.8. At lower acidic pHs than 6.8, it is in form of NRH$^+$ while it is in form of NR at basic pHs. At pH 8.0, As(III) is predominantly in neutral form of As(OH)$_3$/AsO(OH) with a pK$_a$ value of 9.3 whereas As(V) is predominantly in ionic form of AsO$_3$(OH)$_2$ or AsO$_2$(OH)$_2$ with an acid ionization constants of pKa$_1$: 2.24, pKa$_2$: 6.96 and pKa$_3$: 11.50. From prior studies conducted in pH range 3-10, it was observed that As(V) according to As(III) at levels of 10 µg L$^{-1}$ gave selectively a more stable complex with a significant sensitivity difference at pH 8.0. From the literature information’s 25-28 and these findings based on selection of As(V) as analyte for further studies, it can be concluded that the formed hydrophobic ternary complex is easily and rapidly extracted into the surfactant-rich
phase of PONPE 7.5 under ultrasonic power. The possible complex formation mechanisms based on ion-association between anionic As(V)-Pyrogallol complex and NRH⁺ or acid-base and π-π stacking interactions between As(III)-Pyrogallol condensation adduct and basic dye, NR after reduction of As(V) to As(III) at pH 8.0 may be postulated as follows:

AsO₂(OH)₂⁻ + R(OH)₃ (Pyrogallol) → R(OH)O₂AsO₂⁻ + 2H₂O with condensation at pH 8.0

(1a)

R(OH)O₂AsO₂⁻ + NRH⁺ (acidic form) → [NRH⁺⋯R(OH)O₂AsO₂⁻], ion-pairing complex formation

(1b)

HAsO₄²⁻ + R(OH)₃ + 3H₂O → R(OH)O₂ + As(OH)₃ or AsO(OH)⁺ 2OH⁻, pre-oxidation of Pyrogallol at pH 8.0

(2a)

As(OH)₃ or AsO(OH) + R(OH)O₂ → RO₂As(OH)₂ or RO₂As=O + H₂O

(2b)

RO₂As(OH)₂ or RO₂As=O + NR (basic form) → [RO₂As(OH)₂ or RO₂As=O⋯NR], π-stacking complex formation

(2c)

In speciation study as a consequence of the proposed method to be a selective and sensitive to only As(V), different types of oxidizing agents such as H₂O₂, K₂Cr₂O₇ and KMnO₄ were studied for oxidation of As(III) to As(V) with different advantages and disadvantages. In this study, 1.5×10⁻⁴ mol L⁻¹ of KMnO₄ solution containing 0.25 mol L⁻¹HCl was used as an oxidizing agent which allowed rapid and complete oxidation of As(III) to As(V) at room temperature. After the quantitative oxidation of As(III) to As(V), pH of the solutions was adjusted to 7.0 with diluted NaOH solution (1.0 mol L⁻¹). Then, the proposed method was applied for the determination of the total As by means of FAAS. Also, the concentration of As(III) is calculated from difference between total As and As(V) concentrations.

3. Results and Discussions
The effects of concentrations of reagents and nonionic surfactant, pH, temperature and time of equilibration, centrifugation rate and time on the analytical signal were investigated and optimized in order to reach the best analytical performance for the UA-CPE procedure.

### 3.1. Effect of pH and buffer volume on UA-CPE

The separation of As(V) or As(III) by UA-CPE method involves previous formation of a stable complex, which needs to present sufficient hydrophobicity to be extracted into the small volume of the surfactant-rich phase. Thus, the pH is a critical factor affecting both the reaction between ion-pairing reagent and As(III) or As(V)-Pyrogallol adducts, and the extractability of complex into the surfactant-rich phase for UA-CPE. Thus, in this part of experiment, the effects of different buffers were extensively studied for the extraction and determination of arsenic in the surfactant-rich phase in the range pH 5.5-11.0 (Figure 1). The maximum absorbance was obtained with borate buffer system with a significant sensitivity difference for As(V) at pH 8.0. Below the pH 8.0, extraction efficient is very low because of complex formation is inadequate as a measure of protonation of ion-pairing reagent, NRH\(^+\) and dimerization equilibrium depending on its concentration and pH, 2NRH\(^+\) \leftrightarrow (NRH)\(_2\)\(^{2+}\) or 2NRH\(_2\)\(^{2+}\) \leftrightarrow (NRH\(_2\))\(_2\)\(^{4+}\). It is implied in literature\(^{29,30}\) that the dye in low concentrations of 3.94×10\(^{-5}\) mol L\(^{-1}\) at pH≤ 7.0 is aggregated with a dimerization constant of K\(_D\): 5.31. Also, above pH 8.0, the reason of decrease in extraction efficient can be deprotonation of Pyrogallol to phenolate anion due to slow and incomplete of redox reaction before hydrophobic complex. Hence, an optimal value was selected as a pH of 8.0 in order to give the highest sensitivity. Furthermore, the concentration of borate buffer solution as a function of volume of buffer solution at a fixed concentration on the analytical signal was also studied in range of 0.5–4.0 mL, and the best analytical signal was obtained by using 2.0 mL buffer solution in final volume of 50 mL.

### 3.2. Effect of complexing agents volume on UA-CPE

The UA-CPE efficiency depends on the hydrophobicity of the ligand and the complex formation. Hence, the effect of the volume of the NRH\(^+\) at fixed concentration of 1.0×10\(^{-3}\) mol L\(^{-1}\) on the analytical signal was examined in range of (0.0–4.0) mL and the results were illustrated in Figs. 2. It could be seen that the signal intensity of As(V) strongly depended on the amount of NRH\(^+\). With the volume of NRH\(^+\) increased from 0.0 to 1.25 mL, the signal intensity initially increased, and maximum signal intensity was achieved after the amount of the NRH\(^+\) approached to 1.25 mL at fixed concentration of 1.0×10\(^{-3}\) mol L\(^{-1}\) and then
gradually decreased due to degradation of ligand. Thus, 1.25 mL of $1.0 \times 10^{-3}$ mol L$^{-1}$NRH$^+$ was selected as optimal value for further studies.

The variation of the analytical signal as a function of the volume of Pyrogallol at fixed concentration of $1.0 \times 10^{-3}$ mol L$^{-1}$ in the presence of 10 µg L$^{-1}$As(V) was studied in range of (0.0–4.0) mL, and the results in Figs. 2 indicated that the signal intensity of the analyte linearly increases with Pyrogallol volume up to 1.75 mL. The maximum signal intensity linearly decreased with increasing slope at the higher volumes. The cause of this decrease in signal may be complexation of Pyrogallol based on acid-base and $\pi$-stacking interactions with NRH$^+$ in absence of As(V) due to increase in blank signal. So, a Pyrogallol volume of 1.75 mL at fixed concentration of $1.0 \times 10^{-3}$ mol L$^{-1}$ was selected as optimal value for further studies.

### 3.3. Effect of amount of nonionic surfactant on UA-CPE

In UA-CPE choosing an appropriate surfactant is important, since the temperature corresponding to cloud point is correlated with the hydrophilic property of a surfactant. A successful CPE should maximize the extraction efficiency by minimizing the phase volume, thus increasing its concentrating capability. To the present time, non-ionic surfactants (mainly polyoxy ethylenated alkylphenols) such as Ponpe 7.5, Tween series and Triton series are those most widely employed for metal analysis with UA-CPE. The surfactants are commercial availability, high purity grade, stable, non-volatile, relatively non-toxic and eco-friendly reagents. In the preliminary experiments, it is observed that the addition of the nonionic surfactants such as Triton X-45, Triton X-114 and PONPE 7.5 to ternary complex system of As(III) or As(V) and heating the solution provides a successful extraction in Figure 3. Therefore, the effect of volume of the surfactants at fixed concentration 5.0 % (v/v) on the analytical signal of 10 µg L$^{-1}$ was examined in range of (0.0–3.0) mL. The best quantitative extraction was observed with 0.6 mL of 2.5 % (v/v) PONPE 7.5. This value corresponds to a maximum concentration of 0.0306 % (w/w) PONPE 7.5 above its critical micelle concentration of 0.009 % (w/w). Therefore, 0.6 mL of 2.5 % (v/v) PONPE 7.5 was selected as optimal value for further studies.

### 3.4. Effect of salting out agent concentration on UA-CPE

Studies on the effects of some additives, such as anionic, non-ionic surfactants and inorganic electrolytes such as NaCl, KCl, Na$_2$SO$_4$ and NH$_4$Cl, on the cloud point behavior of non-ionic...
surfactants have been reported.\textsuperscript{31-33} It was observed that the presence of electrolytes decreases the cloud point (salting-out effect), resulting in a more efficient extraction. The lower cloud point is attributed to electrolytes promoting dehydration of the poly (oxyethylene) chains. According to Komaromy-Hiller, the salting-out phenomenon is directly related to desorption of ions to the hydrophilic parts of the micelles, increasing interaction between micelles and consequently leading to the precipitation of surfactant molecules. Based on this discussion, the influence of ionic salts strength such as NaCl, KCl, Na\textsubscript{2}SO\textsubscript{4} and NH\textsubscript{4}Cl on extraction efficiency was studied in the range of (0.0–2.0) mL at a fixed inorganic salts concentration of 0.01 mol L\textsuperscript{-1} under the optimized reagent conditions. The maximum absorbance was obtained at 0.75 mL of 0.01 mol L\textsuperscript{-1}Na\textsubscript{2}SO\textsubscript{4} as sensitivity enhancement agent. The absorbance considerably decreased for increasing Na\textsubscript{2}SO\textsubscript{4} volumes in range of 0.75–2.0 mL. This effect might be explained by the additional surface charge when the Na\textsubscript{2}SO\textsubscript{4} concentration is very high, thus changing the molecular architecture of the surfactant and consequently the micelle formation process. It is necessary to emphasize that different blank solutions were also evaluated and no significant signal was obtained. Therefore, 0.75 mL of 0.01 mol L\textsuperscript{-1}Na\textsubscript{2}SO\textsubscript{4} was selected as optimal value for further studies.

3.5. Effects of equilibrium temperature and sonication time

Equilibrium temperature and time are important parameters to complete quantitatively the complex formation and achieve an easy phase separation and preconcentration on UA-CPE. Due to ultrasonic cavitation, ultrasound can accelerate the interactive rate between the surfactant and aqueous phase, so that the target analyte could be well extracted into the surfactant-rich phase. Hence, the effect of equilibrium temperature was investigated in range of 30-60 °C under ultrasonic power (300 watt, 40 Hz). As a result of experimental studies, the solutions became turbid as soon as the solutions were put into the ultrasonic bath with temperature higher than 35 °C. The temperature had no considerable effect upon the extraction efficiency and the analytical signal kept constant at temperature range of 30–60 °C. Keeping the equilibrium temperature of 35 °C, the influence of sonication time on UA-CPE was investigated in range of 2–30 min. It was seen that, 5 min was sufficient to achieve a quantitative extraction of As(V). Thus, 35 °C and 5 min at fixed ultrasonic power (300 watt, 40 Hz) were chosen as the equilibrium temperature and sonication time for the propose UA-CPE method respectively.

3.6. Effects of centrifugation rate and time
Centrifuge time and rate are very necessary to preconcentrate trace amounts of As(V) with high efficiency in a short time. Thus, under optimal conditions obtained, the effect of the centrifuge time and rate were studied in range of 2-20 min and 500-4000 rpm, respectively. The results showed that centrifugation for 5 min at 4000 rpm and cooling for 10 min in an ice-bath leads to the maximum recovery and sensitivity for As(V).

### 3.7. Selection of diluting agent

The volume of the surfactant-rich phase acquired after UA-CPE is very viscous and small for detection by FAAS. Thus, before detection by FAAS the volume of the surfactant-rich phase can be decreased using diluting agents. It is very important to choose the suitable solvent for maximum extraction efficiency. The effect of various solvents such as methanol, acetone, acetonitrile, acidic methanol, acidic ethanol, ethanol and THF in range of 0.5-2.0 mL was studied to obtain the maximum analytical sensitivity and the best regression coefficient, $r^2$ after UA-CPE. The best absorbance as a measure of analytical sensitivity (m/s) and regression coefficient ($r^2$) was obtained in the presence of surfactant-rich phase diluted to 1.0 mL with methanol containing 1.0 mol L$^{-1}$ HNO$_3$ from calibration curves obtained for fixed As(V) concentrations of 5, 15 and 25 µg L$^{-1}$.

### 4. Optimization of oxidation of As(III) to As(V) and determination of total As

Different types of oxidizing agents such as H$_2$O$_2$, K$_2$Cr$_2$O$_7$ and KMnO$_4$ have been studied for oxidation of As(III) to As(V) with different advantages and disadvantages. In this study, 1.5×10$^{-4}$ mol L$^{-1}$ of KMnO$_4$ solution containing 0.25 mol L$^{-1}$HCl was used as an oxidizing agent which allowed rapid and complete oxidation of As(III) to As(V) at room temperature out of any interfering of excess amount of KMnO$_4$ in total As determination step. Effect of KMnO$_4$ concentration at fixed concentration of 0.25 mol L$^{-1}$ HCl was examined in the range of (0.1-3.0)×10$^{-4}$ mol L$^{-1}$ for oxidation of 25 µg L$^{-1}$ As(III) with oxidation time of 5 min. It was found that KMnO$_4$ concentration is enough 1.5×10$^{-4}$ mol L$^{-1}$ in order to completely oxidize As(III) to As(V). After pre-oxidation, the mixtures were analyzed by proposed method to determine the total As levels.

The proposed UA-CPE/FAAS method was studied for speciation of the inorganic As species after oxidation of As(III) to As(V) using a KMnO$_4$ solution. For this step, the changing concentrations of As (III) in the range of 5–100 µgL$^{-1}$ in the presence of the fixed As(V) concentration of 5 µgL$^{-1}$ were spiked into the solution media. After oxidation with
KMnO$_4$, total speciation analysis was also made by using FAAS based on preconcentration with UA-CPE under optimum conditions. The amount of As(III) ions were calculated from the difference between the amounts of As(V) and total As before and after oxidation due to give more reliable results. The same procedure was applied to determine the inorganic As species in real samples. The speciation results are given in Table 1. As can be seen from Table 1, the recoveries were reasonable for trace analysis, ranging from 98.2 % to 101 %. The REs and RSDs for five replicate measurements in range of 5-100 µgL$^{-1}$ As(III) in the presence of 5 µgL$^{-1}$ As(V) were between –(1.3–4.0) % and 2.2–4.1 %, respectively.

5. Interference study

Interfering ions may react with NRH$^+$ or Pyrogallol and may decrease the formation of hydrophobic complexes with As(V) and NRH$^+$. Thus, the effects of foreign ions on the preconcentration and determination of 20 µgL$^{-1}$ of As(V) under the optimized conditions by the proposed method were investigated. The tolerance limit was identified as the concentration of added ion that caused greater than ± 5.0 % relative error. As can be seen from Table 2, the results demonstrated that large excess most of the cations and anions did not interfere on the determination of 20 µgL$^{-1}$ of As(V). At initial, in order to suppress the effect of possible interfering cations, which can be available in sample matrix including solid SRM, samples were passed through a chelating cation-exchange resin acting as an anion-exchange resin ≤ pH 4.0 and a cation-exchange resin between pH 4.0-7.0. Thus, their interfering effects greatly were reduced for accurate and reliable determination of As(V) in real samples. Additionally, the interfering effects of interfering anionic and cationic species such as Cr$^{3+}$, Fe$^{2+}$, Fe$^{3+}$ and C$_2$O$_4^{2-}$ can be efficiently removed by the addition of suitable masking agents to the solution before preconcentration with UA-CPE. The results clearly point out the analytical performance of the propose method for real sample applications.

6. Analytical figures of merits

In order to evaluate the developed method, a series of experiments have been carried out under the optimized conditions. The calibration curve was constructed after preconcentration with UA-CPE. A good linear response was obtained in range of 1.5-170 µgL$^{-1}$ with regression coefficient of 0.9967 for As(V). After optimization studies by FAAS based on improvement of selectivity with a suitable reagent and pH for As(V) instead of selective detection tool such as HG-AAS, the limits of detection (LOD) and quantification (LOQ), which are defined as 3σ$_{\text{blank}}$/m and 10σ$_{\text{blank}}$/m (n: 10) (where σ$_{\text{blank}}$ is the standard deviation of
twelve replicate measurements of the blank and m is the slope of the calibration curve) were 0.45 and 1.5 µg L\(^{-1}\), respectively. Also, the RSDs as a measure of precision for 5 replicate determinations of 5, 20 and 50 µg L\(^{-1}\) of As(V) were in the range of 2.2-4.7 %. The preconcentration factor (PF), which is calculated as the concentration ratio of analyte in the final diluted surfactant rich extract ready for FAAS determination and the initial solution was averagely 50 for As(V). The sensitivity enhancement factor (EF) was 47.3, which was calculated by using the ratio between the slopes of calibration curves obtained with and without the preconcentration with UATCPE.

6.1. Accuracy of the UA-CPE method and analytical applications

The accuracy of the method was analyzed two SRMs: SRM 1575a (pine needles) and SRM-1643e (trace elements in water) after dilution of 15-fold and the results seen in Table 4(a). As can be seen from Table 4(a), the observed values (39.4±0.8 and 58.3±1.0 µg kg\(^{-1}\) or µg L\(^{-1}\) for five replicate measurements) found by using UA-CPE–FAAS for SRM 1575a pine needles and SRM-1643e trace elements in water were statistically in good agreement with the certified values of 39.0±2.0 and 59.0± 0.7 µg L\(^{-1}\). As the certified values were within the 95 % confidence interval about the mean of the experimentally determined values, there is no significant difference between the values. It can be concluded that the proposed method is accurate and free from systematic errors. Also, in order to confirm the accuracy of the proposed method, spiking was performed in five replicate at three concentration levels (5, 20 and 50 µg L\(^{-1}\)) of As(V) for both SRMs. As a result, it has been found that the recoveries are highly quantitative in range of 98.6–101 % with a RSD ranging from 0.8 to 1.7 % for total As. The applicability of the method was successfully investigated by determining of inorganic As species in selected water and beverages. The beverages were pretreated with extraction under microwave and ultrasonic powers, according to procedure explained in preparation of water and beverage samples to analysis. 5.0 mL of the prepared solution samples were individually transferred into volumetric tubes of 50 mL. Then, the proposed method at levels of 5, 10 and 50 µg L\(^{-1}\)As(V) was applied to determine the amounts of As(V) by using the standard addition method. After oxidation of As(III) to As(V), the method was applied to determine the amount of total As. The amount of As(III) was determined by calculating the difference between total As and As(V). The results for the beverages analyzed using the evaluated UA-CPE–FAAS method are shown in Table 4(b). In any event, the calibration was attained using the aqueous standard calibration curves. The recoveries from spiked solutions were varied in the range of 98–104 % for microwave-assisted extraction and 98–103 % for ultrasonic-
assisted extraction. Also, the method has directly been applied for the determination of As(V), As(III) and total As in both hot- and cold-spring water including drinking water samples. Because the inorganic As contents of samples are below the method quantification limit, instead of direct calibration curve approach, the As(V) and total As contents of samples were established by using standard addition calibration curves of spiked samples at levels of 5, 10 and 15 µg L\(^{-1}\) As(V) before and after pre-oxidation with KMnO\(_4\) in acidic media. Additionally, the recovery experiments of spiked As(V) at levels of 5, 10 and 50 µg L\(^{-1}\) were carried out by using calibration curve method, and the results are shown in Table 4 (c). The results indicated that the recovery rates are quantitatively at reasonable levels for trace As analysis, ranging from 96.7 to 103 %.

6.2. The comparison of proposed method with the methods published in literature

In the light of all these results, the proposed UA-CPE method gives low LOD (0.45 µg L\(^{-1}\)), good RSDs (2.7-4.2 %), linear working range (from 1.5 to 170 µg L\(^{-1}\)), good preconcentration (50) and sensitivity enhancement factor (43.2) according to SPE,\(^{19}\) SPME,\(^{21}\) LLME\(^{22}\) and coprecipitation\(^{23}\) methods reported in literature. Moreover, from literature information’s, a sensitivity improvement has been achieved by the method when compared to previously reported using works UV–Vis including FAAS, HG-AAS, HG-AFS, ET-AAS, ICP-OES and ICP-MS.\(^{13, 34-39}\) Moreover, the instruments such as ET-AAS, HG-AAS, ICP-OES and ICP-MS are expensive, time-consuming and need expert user in her/his area. Unlike these techniques, FAAS is a simple, cheap, easy operated, rapid response time, available element-selective instrument in many laboratories. Also, the detection limit of the method is lower than those of the reported other methods. As a result, the proposed method is versatile for analysis of trace inorganic As contents of selected water and beverage samples. Moreover, the presented study can also be extended to the other complex matrices and possible sources of contamination.

7. Conclusions

Because there are at lower amounts of inorganic As species in water and beverage samples, it usually needs a preconcentration step or more sensitive analytical instrumentation such as ETV-ICP-OES, ICP-MS, HG-ICP-OES, which are very expensive. Thus, in the present study, a new UA-CPE method for the determination of inorganic As species in the samples is described and evaluated by a conventional FAAS. The method allows arsenic detection at 0.15 µg L\(^{-1}\) levels in a wide linear range of 113-fold, thus represents a promising approach in
the monitoring of toxic inorganic As in the real samples. Advantages of the UA-CPE methodology are easy, safe, rapid and inexpensive. Also, FAAS is a comparatively simple, economical and a versatile element-selective detection tool, which can be available in nearly every research laboratory. So, it can be considered an alternative to expensive and time-consuming analytical techniques such as ICP-MS, ETV-ICP OES, ICP-AES, HG-ICP-OES and ET-AAS. Moreover, NRH\(^+\) forming a stable ion-pairing complex and/or \(\pi\)-stacking complex with As(V) or As(III) in the presence of Pyrogallol at pH 8.0 was for the first time studied for selective determination of As(V) in selected water and beverages. The results clearly show the potential and versatility of the method, which could be applied to the selective detection of As(V) in presence of excess As(III) in the different complex matrices.

</tbody>
</table>

* The percent recoveries obtained for five replicate measurements and calculated as: % Recovery = \( \frac{C_{\text{after spiking}}}{C_{\text{initial}}} + C_{\text{spiked}} \times 100 \)

** The values found by means of standard addition calibration curves of spiked samples at levels of 5, 10 and 15 µg L\(^{-1}\) As(V) before and after pre-oxidation with KMnO\(_4\) in acidic media.
