This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
A mercury (II) ion sensor device based on an organic field effect transistor with an extended-gate modified by dipicolylamine

Tsuyoshi Minami,* Yui Sasaki,a Tsukuru Minamiki,a Petr Koutnik,b Pavel Anzenbacher, Jr.b and Shizuo Tokitoa

Herein, we report an organic field effect transistor (OFET) with an extended-gate modified by an artificial receptor for the detection of mercury (II) ion (Hg^{2+}) in water. The sensor device is easy-to-fabricate, reusable, disposable, and portable. Thus OFET sensors could be applied for low-cost on-site detection of Hg^{2+}. Heavy metal pollution is one of the significant environmental problems. Mercury, which is found as metallic, inorganic, and organic forms, is recognised as a highly toxic pollutant. Mercury (II) ion (Hg^{2+}) may be converted into organic mercuric compounds, causing damage in organs such as brain, kidney, liver and nervous systems. Hence, the detection of Hg^{2+} is very important for preservation of healthy lives. Although several highly sensitive and accurate methods such as atomic absorption spectrometry (AAS), atomic fluorescence spectrometry (AFS), and inductively coupled plasma mass spectrometry (ICP-MS) have been developed, these methods are high-cost, and their application is time-consuming and requires sophisticated instrumentation. Thus, simpler and easier methods are desirable. Toward this end, colourimetric, fluorometric or electrochemical Hg^{2+} detection based on supramolecular interactions is vigorously researched. In many cases, their sensitivity and selectivity for Hg^{2+} has been mainly investigated. However, the manufacturing costs of the Hg^{2+} sensors have not been discussed. Although some unique and intriguing Hg^{2+} sensors could be found, their potential industrial mass production seems difficult. In this regard, we strongly believe that organic field effect transistors (OFETs) are one of the prospective candidates for the sensing of Hg^{2+}. Based on solution-processes, the OFETs can be fabricated on various types of substrates including plastic films, glass, and paper, etc. The photolithography, crystallisation at high temperature, or silicon substrates are not required, which means that the fabrication of OFET-sensors is easy, environmentally-friendly and low-costs. Although a heavy metal ion sensor based on an OFET modified with a DNA-probe has been recently reported, OFET sensors modified with artificial receptors for Hg^{2+} are underdeveloped. Here, we report the first extended-gate type OFET sensor for the Hg^{2+} detection in aqueous media. The fabricated OFET possesses a thiolated-dipicolylamine (DPA) derivative which can coordinate mercury (II) ion.

Fig. 1 Schematic structure of the Hg^{2+} sensor based on the extended-gate type OFET. The extended-gate electrode is modified with dipicolylamine self-assembled monolayer. A photograph shows the fabricated sensing devices (six devices in the picture). The scale bar corresponds to 2 cm.
The electric properties of the DPA-modified extended gate OFET were investigated, revealing that the device could operate at below 1 V. In addition, repetitive measurements showed that the OFET was stable against the bias stress. (See the ESI). Based on these results, we concluded that the OFET can be employed as a heavy metal ion sensor.

Next, we attempted to detect Hg\textsuperscript{2+} in water. The extended-gate electrode was immersed in an aqueous solution of Hg(NO\textsubscript{3})\textsubscript{2}. The gate voltage was applied through a silver/silver chloride electrode (Fig. 1). Figs. 2a exhibits the output characteristics of the OFET upon addition of incremental amounts of Hg\textsuperscript{2+} in a HEPES (= 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid) buffer solution with NaCl (100 mM), pH 7.4 at r.t. As a result, the output current decreased with increased the concentration of Hg\textsuperscript{2+}. Fig. 2b summarises the relationship between the Hg\textsuperscript{2+} concentration and change in the output current. The function mechanism of extended-gate type FETs is based on a shift in the surface potential at the gate electrode/solution interface.\textsuperscript{12} The channel conductance of the extended-gate type FETs is mainly determined by the potential difference between the reference and the extended-gate electrodes. Thus, these observed changes of the output current stem from changes in conductance within the OFET channel induced by the positively charged mercury ions (Hg\textsuperscript{2+}) captured on the extended-gate electrode (Fig 3). As an evidence of the capture of Hg\textsuperscript{2+} by DPA, we measured X-ray photoelectron spectroscopy (XPS) of the extended-gate electrode after the immersion in the Hg\textsuperscript{2+} solution. As expected, XPS indicated the presence of mercury with its expected binding energy (Fig. 2c), which strongly supported that the electrical changes in the OFET characteristics were caused by the captured Hg\textsuperscript{2+}. Furthermore, it is worth noting that the detection of Hg\textsuperscript{2+} was successfully achieved even in the presence of large excess of interferent Na\textsuperscript{+} (100 mM).

The detection limit\textsuperscript{13} of Hg\textsuperscript{2+} was estimated to be 9.9 ppb, which is comparable to or lower than those of recent reported sensors based on colourimetric,\textsuperscript{14} fluorometric,\textsuperscript{15} and electrochemical\textsuperscript{16} systems. Although the detection limit is slightly higher than WHO’s guideline value for inorganic mercury in drinking water,\textsuperscript{17} the further improvement of sensitivity could be attained by OFET-based electronic circuits such as amplifiers.\textsuperscript{18}

The next step was to investigate the selectivity of the OFET sensor device toward various metal ions. The extended-gate electrode of the OFET was immersed in the aqueous solutions of metal ions (such as Zn\textsuperscript{2+}, Ni\textsuperscript{2+}, Co\textsuperscript{2+}, Cd\textsuperscript{2+}, Cu\textsuperscript{2+}, Mg\textsuperscript{2+}, Ga\textsuperscript{3+}, and Al\textsuperscript{3+}) (3 μM) and the output current was measured. The OFET modified with DPA receptor senses the metal ions in the following order: Hg\textsuperscript{2+} >> Cu\textsuperscript{2+} > Zn\textsuperscript{2+}, Ni\textsuperscript{2+} ≥ Cd\textsuperscript{2+} > other metal ions (Co\textsuperscript{2+}, Mg\textsuperscript{2+}, Ga\textsuperscript{3+}, and Al\textsuperscript{3+}). The strongest response of the OFET to metal ions was to Hg\textsuperscript{2+} while Cu\textsuperscript{2+}, Zn\textsuperscript{2+}, Ni\textsuperscript{2+}, and Cd\textsuperscript{2+} showed weak response (See the ESI). These responses are arising from the binding affinity of DPA for heavy metal ions. To improve the selectivity, we decided to add pyridine-2,6-dicarboxylic acid (PDCA)\textsuperscript{19} in the sensing system. PDCA is a chelating agent that forms complexes with heavy metal ions
such as Cu^{2+}, Zn^{2+}, Ni^{2+}, and Cd^{2+}. On the other hand, PDCA does not have an appreciable affinity to Hg^{2+} in aqueous solutions, suggesting that the chelating ability of PDCA would be very suitable to improve the selectivity of the OFET sensor. As expected, the response to Cu^{2+}, Zn^{2+}, Ni^{2+}, and Cd^{2+} was dramatically decreased in the presence of PDCA, while we still observed significant changes in the output current upon addition of Hg^{2+} (Fig. 4). It is noteworthy that our sensing system based on the OFET with DPA does not require any biomolecules (e.g. DNA probes, enzymes, or antibodies), which implies higher chemical stability in a long-term use and storage.

To confirm further practical utility of the sensing system, a competitive experiment was carried out. We attempted to detect Hg^{2+} in an aqueous solution in the presence of 9 competing metal ions (Zn^{2+}, Ni^{2+}, Co^{2+}, Cd^{2+}, Cu^{2+}, Mg^{2+}, Na^{+}, Ga^{3+}, and Al^{3+}). The OFET with PDCA showed a clear response to Hg^{2+} even in the presence of competitive metal ions. (See the ESI). This confirmed that the effect of potentially interfering ions in the Hg^{2+} sensing is almost negligible.

Finally, we have investigated the reusability of the OFET sensor device. The electrical response could be recovered by rinsing of the extended-gate electrode with an aqueous solution of ethylenediaminetetraacetic acid (EDTA). The reusability was investigated by alternatively immersing the electrode in an aqueous solution containing Hg^{2+} and EDTA, which resulted in an efficient electrical switching. As illustrated in Fig. 5, the drain current could be recovered when the electrode was immersed in EDTA solution for 20 min at r.t. This is a result of a competitive binding between the DPA and EDTA toward Hg^{2+}. This suggests that the device is reusable and also that no dramatic degradation of the OFET takes place in repeated use.

**Fig. 5.** Changes in the output current upon alternating treatment by aqueous solutions of Hg^{2+} and EDTA. The standard deviation of each response is < 2%.

In summary, we have successfully developed a reusable Hg^{2+} sensing system based on an extended-gate type OFET. The sensitivity of the fabricated OFET is comparable to or higher than those of optical or electrochemical sensing systems. Importantly, the extended-gate electrode was fabricated on a plastic film, suggesting that the fabricated electrode could be used in a disposable fashion. Thus, our preliminary results indicate that the extended gate OFETs could open up a new avenue in the development of low-cost, reusable and disposable Hg^{2+} sensor devices. Furthermore, modifications of the periphery of the OFET could yield more efficient systems. Experiments to this effect are in progress in our laboratory.

We gratefully acknowledge the financial support from the Japan Society for the Promotion of Science (JSPS, Grant-in-Aid for Research Activity Start-up, No. 26888002), Kurita Water and Environment Foundation Grant, Kato Foundation for Promotion of Science, and the Japan Science and Technology Agency (JST, the Center of Innovation Program). We also thank Dr. D. Yokoyama, Dr. K. Fukuda, Dr. D. Kumaki and T. Sekine of Yamagata University for their technical support and valuable feedback.
