This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms \& Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

# Icosahedral metallacarborane/carborane species derived from 1,1'-bis(o-carborane) $\dagger$ t 

Gobika Thiripuranathar, Wing Y. Man, Cesar Palmero, Antony P. Y. Chan, Bernhard T. Leube, David Ellis, David McKay, Stuart A. Macgregor, Laure Jourdan, Georgina<br>M. Rosair and Alan J. Welch*

Singly-metallated derivatives of $1,1^{\prime}$-bis ( $o$-carborane) with both $\{\mathrm{Ru}($ arene $)\}$ and $\{\mathrm{CoCp}\}$ fragments have been prepared and characterised; with $\{\mathrm{Ru}(\mathrm{p}-\mathrm{cymene})\}$ both unisomersied and isomerised species are formed and the former is easily converted to the latter with mild heating, whereas the product obtained with $\{\mathrm{CoCp}\}$ depends upon the source of that fragment and a redox step is required to effect the isomerisation.

[^0]
#### Abstract

Examples of singly-metallated derivatives of $1,1^{\prime}-\operatorname{bis}(o$-carborane) have been prepared and spectroscopically and structurally characterised. Metallation of [7-( $1^{\prime}-1^{\prime}, 2^{\prime}-$ closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$ 7,8 -nido- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]^{2-}$ with a $\{\mathrm{Ru}(p \text {-cymene })\}^{2+}$ fragment affords both the unisomerised species [1-( $1^{\prime}-1^{\prime}, 2^{\prime}$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-3$-( $p$-cymene)-3,1,2-closo $\left.-\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$ (2) and the isomerised [8( $1^{\prime}-1^{\prime}, 2^{\prime}$-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}$ )-2-( $p$-cymene)-2,1,8-closo- $\left.\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right] \quad$ (3), and $\quad 2$ is easily transformed into $\mathbf{3}$ with mild heating. Metallation with a preformed $\{\mathrm{CoCp}\}^{2+}$ fragment also affords a 3,1,2-MC ${ }_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ product [1-(1'-1',2'-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-3-\mathrm{Cp}-3,1,2$-closo$\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ (4), but if $\mathrm{CoCl}_{2} / \mathrm{NaCp}$ is used followed by oxidation the result is the $2,1,8-$ $\mathrm{CoC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ species [8-( $1^{\prime}-1^{\prime}, 2^{\prime}$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-2-\mathrm{Cp}-2,1,8$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (5). Compound $\mathbf{4}$ does not convert into $\mathbf{5}$ in refluxing toluene, but does do so if it is reduced and then reoxidised, perhaps highlighting the importance of the basicity of the metal fragment in the isomerision of metallacarboranes. A computational study of $1,1^{\prime}$-bis(o-carborane) is in excellent agreement with a recently-determined precise crystallographic study and establishes that the $\left\{1^{\prime}, 2^{\prime}\right.$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right\}$ fragment is electron-withdrawing compared to H .

## Introduction

$1,1^{\prime}$-bis(o-carborane), the trivial name for [1-(1'-1', $2^{\prime}$-closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$-1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}$ ] (Fig. 1), is the simplest bis(carborane) species, comprising two ortho-carborane units connected by a $\mathrm{C}-\mathrm{C}$ bond. ${ }^{1}$ It was first synthesised by insertion of diacetylene into $\mathrm{B}_{10}$ frameworks ${ }^{2}$ but it is also produced from the $\mathrm{CuCl}_{2}$-mediated coupling reactions of mono- or di-lithiated salts of ortho-carborane, ${ }^{3}$ although yields by this route are somewhat compromised by the additional formation of $\mathrm{C}-\mathrm{B}$ and $\mathrm{B}-\mathrm{B}$ linked isomers. $\mathrm{CuCl}_{2}$-coupling was also used to make $1,1^{\prime}$-bis( $m$-carborane) ${ }^{3,4}$ and $1,1^{\prime}$-bis $\left(p\right.$-carborane), ${ }^{4,5}$ the latter an important starting point for the construction of "carborods", rigid-rod oligomers of paracarborane. Reference 5(a) also notes that $1,1^{\prime}$-bis(p-carborane) can be prepared by $\mathrm{CuCl}-$ coupling, an idea subsequently used by Xie to afford an improved yield of $1,1^{\prime}$-bis ( $o$ carborane). ${ }^{6}$
<Fig. 1 near here>
Although 1,1'-bis(o-carborane) has been known for many years, its chemistry remains underdeveloped. Double deprotonation forms a dianionic chelating ligand which has been used to complex a variety of transition-metal cations ${ }^{7}$ and also an $\left\{\right.$ AsMe \} fragment. ${ }^{8}$ Monoand di-deboronation (single and double "decapitation", respectively) of 1,1'-bis(o-carborane) has also been reported. ${ }^{9}$ In addition, $1,1^{\prime}$-bis( $o$-carborane) has been reduced with both 2 e and $4 \mathrm{e} .{ }^{10}$ In solution, $\left[\mathrm{PPh}_{3} \mathrm{Me}\right]^{+}$and $\left[(15-c r o w n-5)_{3} \mathrm{Na}_{2}\right]^{2+}$ salts of the 2 e reduced species are identical, whilst in the solid state the anion of the $\left[\mathrm{PPh}_{3} \mathrm{Me}\right]^{+}$salt has two partially-open 4atom CBCB faces ${ }^{11}$ and the anion of the the $\left[(15 \text {-crown- } 5)_{3} \mathrm{Na}_{2}\right]^{2+}$ salt has one 4 -atom CBCB face which is partially-open and one 5 -atom CBCBB face which is rather more open. ${ }^{10}$ Double protonation of the 4 e reduced form and subsequent work-up caused the linking C atoms to adopt bridging positions on $\mathrm{B}-\mathrm{B}$ edges above nido 11 -vertex cages, in a similar manner to the protonation and work-up of [7,9-nido- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}\right]^{2-}$ affording $\left[\mu_{9,10}-\mathrm{CH}_{2}-7\right.$-nido$\left.\mathrm{CB}_{10} \mathrm{H}_{11}\right]^{-}$. ${ }^{12}$

Prior to our recent research ${ }^{13,14}$ the only metallacarboranes derived from bis(carboranes) of which we are aware are two $2,1,8-\mathrm{MC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ species ${ }^{15,16}$ and two $\operatorname{bis}\left(\right.$ metallacarboranes ), ${ }^{17}$ one of $3,1,2-\mathrm{MC}_{2} \mathrm{~B}_{9}-3^{\prime}, 1^{\prime}, 2^{\prime}-\mathrm{MC}_{2} \mathrm{~B}_{9}$ geometry and the other of 3,1,2$\mathrm{MC}_{2} \mathrm{~B}_{9}-2^{\prime}, 1^{\prime}, 8^{\prime}-\mathrm{MC}_{2} \mathrm{~B}_{9}$ geometry. ${ }^{18}$

Recently we explored the consequences of 4 e reduction and metallation of bis $(o$ carborane). Reduction and metallation with $\{\operatorname{Ru}(p \text {-cymene })\}^{2+}$ fragments ( $p$-cymene $=\eta$ $\mathrm{C}_{10} \mathrm{H}_{14}, \quad 1-{ }^{\mathrm{i}} \mathrm{Pr}, 4-\mathrm{MeC}_{6} \mathrm{H}_{4}$ ) led unexpectedly to a 13-vertex metallacarborane/12-vertex carborane species and cleavage of an aromatic $\mathrm{C}-\mathrm{C}$ bond under ambient conditions. ${ }^{13}$ Reduction and metallation with $\{\mathrm{CoCp}\}^{2+}$ fragments $\left(\mathrm{Cp}=\eta-\mathrm{C}_{5} \mathrm{H}_{5}\right)$ afforded racemic and
meso diastereoisomers of the 13-vertex metallacarborane/13-vertex metallacarborane species
[1-(1'-4'-Cp-4', 1',6'-closo- $\left.\mathrm{CoC}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-4-\mathrm{Cp}-4,1,6$-closo- $\left.\mathrm{CoC}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right]$. ${ }^{14}$
In this contribution we report the monodeboronation and subsequent metallation with \{ML\} fragments $\left(\mathrm{L}=\eta\right.$-bonded polyene) of $1,1^{\prime}$-bis $(o$-carborane) leading to 12 -vertex metallacarborane/12-vertex carborane products with both non-isomerised [1-(1'-1', $2^{\prime}$-closo$\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$-3-L-3,1,2-closo- $\mathrm{MC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] and isomerised [8-(1'-1', $2^{\prime}$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$-2-L-2,1,8closo $-\mathrm{MC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] architectures. We describe detailed spectroscopic and structural studies of these products and investigate the isomerisation between them.

## Results and Discussion

Monodeboronation of $1,1^{\prime}$-bis(o-carborane) with one equivalent of KOH in refluxing EtOH , according to the procedure outlined by Hawthorne et al, ${ }^{9}$ followed by cation metathesis, afforded the anion [7-( $1^{\prime}-1^{\prime}, 2^{\prime}-$ closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-7,8$-nido $\left.-\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{-}\left([\mathbf{1}]^{-}\right)$, as either the $\left[\mathrm{HNMe}_{3}\right]^{+}$or $[\mathrm{BTMA}]^{+}$salt $\left(\mathrm{BTMA}=\right.$ benzyltrimethylammonium) in good yields. The ${ }^{1} \mathrm{H}$ NMR spectrum of $[\mathbf{1}]^{-}$shows, in addition to the resonances associated with the appropriate cation, two $\mathrm{CH}_{\text {cage }}$ resonances of equal integral at $\delta \mathrm{ca} .4 .4$ and 2.0 ppm . The former is assigned to the $\left\{\right.$ closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10}\right\}$ component and the latter to the $\left\{\right.$ nido $\left.-\mathrm{C}_{2} \mathrm{~B}_{9}\right\}$ component with reference to the spectra of $1,1^{\prime}$-bis(o-carborane) and $\left[7,8 \text {-nido- } \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-} .{ }^{19}$

The ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of $[1]^{-}$consists of a $1: 1: 1: 5: 2: 3: 2: 1: 1: 1: 1$ pattern between $\delta$ -4 and -36 ppm. A ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}-{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ COSY spectrum of $\left[\mathrm{HNMe}_{3}\right][1]$ in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}$ was obtained in an attempt to assign these resonances to $\left\{\right.$ closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10}\right\}$ or $\left\{\right.$ nido- $\left.\mathrm{C}_{2} \mathrm{~B}_{9}\right\}$ components. By analogy with the spectra of $\left[7,8 \text {-nido- } \mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{12}\right]^{-19}$ and 1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12},{ }^{20}$ it seems reasonable to suggest that the two highest frequency resonances are due to the $\left\{\right.$ closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10}\right\}$ cage and the four lowest frequency resonances are due to the $\left\{\right.$ nido $\left.-\mathrm{C}_{2} \mathrm{~B}_{9}\right\}$ cage, but beyond this it was not possible to deconvolute the entire spectrum of [1] unambiguously.

The salt $\left[\mathrm{HNMe}_{3}\right][\mathbf{1}]$ is a convenient starting point for the synthesis of $\mathrm{MC}_{2} \mathrm{~B}_{9}-\mathrm{C}_{2} \mathrm{~B}_{10}$ products by deprotonation then metallation, following the protocol established for the first metallacarborane by Hawthorne et al. ${ }^{21}$

Following deprotonation of $\left[\mathrm{HNMe}_{3}\right][\mathbf{1}]$ with $n$ - BuLi in THF and addition of $\left[\mathrm{RuCl}_{2}(p-\right.$ cymene) $]_{2}$, yellow [1-( $1^{\prime}-1^{\prime}, 2^{\prime}$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$-3-(p-cymene)-3,1,2-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (2) and colourless $\quad\left[8-\left(1^{\prime}-1^{\prime}, 2^{\prime}\right.\right.$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-2$-( $p$-cymene $)-2,1,8$-closo- $\left.\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}\right]$ (3) were isolated in yields of 8 and $19 \%$, respectively. Both compounds were initially characterised by elemental microanalysis and EI mass spectrometry, the latter clearly showing the molecular ion peaks as a characteristic envelope due to the two naturally-occuring boron isotopes.

In the ${ }^{1} \mathrm{H}$ spectrum of a freshly-prepared $\mathrm{CDCl}_{3}$ solution of 2 are $\mathrm{CH}_{\text {cage }}$ resonances at $\delta$ 4.03 and 3.91 but these are too close to each other to speculate which is due to the carborane and which is due to the ruthenacarborane. The ${ }^{1} \mathrm{H}$ NMR spectrum of 2 also confirms overall molecular asymmetry with a two integral-3 doublets (and not one integral-6 doublet) for the $\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}$ protons of the $p$-cymene ligand. The ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of 2 consists of ten resonances between $\delta 2.8$ and -17.2 with relative integrals 1:1:2:1:2:2:4:2:1:3 from high frequency to low frequency.

With time, solutions of $\mathbf{2}$ show clear evidence for a slow transformation of $\mathbf{2}$ into an isomer 3, a compound which was originally isolated along with 2 from the initial reaction. A THF solution of $\mathbf{2}$ heated to reflux for two hours reveals its complete conversion to $\mathbf{3}$, with
$58 \%$ of the compound being recovered following work-up involving thin layer chromatography (TLC). In 3 there is a significantly greater separation of the $\mathrm{CH}_{\text {cage }}$ resonances, which now appear at $\delta 3.64$ and 2.63. Since only the ruthenacarborane part of 2 has changed in its isomerisation into $\mathbf{3}$ we tentatively assign the lower frequency resonance, $\delta$ 2.63, as arising from $\mathrm{CH}_{\text {cage }}$ in the $\left\{\mathrm{RuC}_{2} \mathrm{~B}_{9}\right\}$ portion of $\mathbf{3}$. Once again the resonances due to the $p$-cymene ligand reveal the overall molecular structure to be asymmetric. In the ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum of $\mathbf{3}$ are ten resonances between $\delta-1.0$ and -20.4 with integrals in the relative ratios 2:2:1:2:1:6:2:1:1:1.

In addition to $\{\operatorname{Ru}(\operatorname{arene})\}^{22}$ a common transition-metal fragment in metallacarborane chemistry is $\{\mathrm{CoCp}\}$. There are two different ways to introduce this fragment to afford a $\mathrm{CpCoC}_{2} \mathrm{~B}_{\mathrm{x}}$ metallacarborane, (i) reaction of the $\left[\mathrm{C}_{2} \mathrm{~B}_{\mathrm{x}}\right]^{2-}$ dianion with $\mathrm{CoCl}_{2} / \mathrm{NaCp}$ (i.e. in situ generation of the $\{\mathrm{CoCp}\}$ fragment) followed by oxidation $\left(\mathrm{Co}^{\mathrm{II}} \rightarrow \mathrm{Co}^{\mathrm{III}}\right)^{23}$ or (ii) reaction of the $\left[\mathrm{C}_{2} \mathrm{~B}_{\mathrm{x}}\right]^{2-}$ dianion with $\left[\mathrm{CpCo}(\mathrm{CO}) \mathrm{I}_{2}\right]$ (i.e. using a "preformed" $\{\mathrm{CoCp}\}$ fragment). ${ }^{24}$ In reaction with $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$ both approaches lead to exactly the same product, but we have found that this is not the case starting from [1] ${ }^{-}$.

Deprotonation of $\left[\mathrm{HNMe}_{3}\right][\mathbf{1}]$ followed by addition of $\left[\mathrm{CpCo}(\mathrm{CO}) \mathrm{I}_{2}\right]$ affords, on work-up, the isomer [1-(1'-1', 2'-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$-3-Cp-3,1,2-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (4) as an orange solid. Microanalysis and mass spectrometry confirm the molecular formula. In the ${ }^{1} \mathrm{H}$ NMR spectrum are three singlets at $\delta 5.86(5 \mathrm{H}, \mathrm{Cp}), 4.24(1 \mathrm{H})$ and $4.03(1 \mathrm{H})$, the last two relatively broad and arising from the cage CH atoms. In the ${ }^{11} \mathrm{~B}$ NMR spectrum are nine resonances in a 1:1:5:1:2:5:2:1:1 pattern, lying between $\delta 6.5$ and -15.9 ppm .

To our surprise, treatment of deprotonated $\left[\mathrm{HNMe}_{3}\right][\mathbf{1}]$ with $\mathrm{CoCl}_{2} / \mathrm{NaCp}$ followed by aerial oxidation yielded an isomer of 4 , the $2,1,8-1^{\prime}, 2^{\prime}$ species [8-( $1^{\prime}-1^{\prime}, 2^{\prime}$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$-2-$\mathrm{Cp}-2,1,8$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (5). This yellow product has, as well as the expected singlet for the Cp protons, cage CH resonances at lower frequency than in $\mathbf{4}, \delta 3.59$ and 2.73. In $\mathbf{4}$ the $\left\{\mathrm{CoC}_{2} \mathrm{~B}_{9}\right\}$ part of the molecule has a $3,1,2-\mathrm{CoC}_{2}$ heteroatom pattern whilst in $\mathbf{5}$ it is $2,1,8-$ $\mathrm{CoC}_{2}$. In the corresponding reference compound [3-Cp-3,1,2-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] the cage CH atoms resonate at $\delta 4.08\left(\mathrm{CDCl}_{3}\right)$ and in [2-Cp-2,1,8-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ ] they resonate at $\delta 2.73$ and $2.47,{ }^{25}$ on the basis of which we tentatively assign the signal at $\delta 2.73$ in 5 to the $\{2,1,8-$ $\mathrm{CoC}_{2} \mathrm{~B}_{9}$ \} fragment. The ${ }^{11} \mathrm{~B}$ NMR spectrum of 5 reveals eleven resonances between $\delta 1.7$ and -17.7 in a $1: 2: 1: 1: 1: 2: 6: 1: 2: 1: 1$ pattern of integrals. Note that in the synthesis of 4 a trace amount of $\mathbf{5}$ is also detected (see Experimental) and that in the synthesis of $\mathbf{5}$ a trace amount of $\mathbf{4}$ is observed.

Given that the $3,1,2-\mathrm{RuC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ species 2 easily transforms to its isomer 2,1,8$\mathrm{RuC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10} 3$ on heating to reflux in THF we attempted to thermally isomerise the $3,1,2-\mathrm{CoC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ species 4 , expecting it to convert into $2,1,8-\mathrm{CoC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10} \mathbf{5}$.

However, even in refluxing toluene for five hours there is no evidence that $\mathbf{4}$ converts into $\mathbf{5}$ by thermolysis. We later show from crystallographic studies that, at least as far as we can tell, compounds $\mathbf{2}$ and $\mathbf{4}$ suffer similar degrees of intramolecular steric crowding, implying that the different isomerisation characteristics of $\mathbf{2}$ and $\mathbf{4}$ cannot be explained by steric factors.

When $[\mathbf{1}]^{2-}$ is treated with $\left[\mathrm{CpCo}(\mathrm{CO}) \mathrm{I}_{2}\right]$ a $\left\{\mathrm{Co}^{\text {III }} \mathrm{Cp}\right\}^{2+}$ fragment is introduced to the dianion, affording the non-isomerised 4. However, when $[\mathbf{1}]^{2-}$ is treated with $\mathrm{CoCl}_{2} / \mathrm{NaCp}$ the reacting fragment is $\left\{\mathrm{Co}^{\mathrm{II}} \mathrm{Cp}\right\}^{+}$. This generates the 19 e monoanion $\left[\mathrm{CpCo}^{\mathrm{II}}\left(\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right)\right]^{-}$, which is then oxidised to the 18 e , isomerised, $\mathrm{Co}^{\text {III }}$ species 5 . We therefore added one equivalent of electrons to $\mathbf{4}$ at room temperature and, after stirring for one hour, oxidised the product aerially. Only $\mathbf{5}$ was detected by ${ }^{1} \mathrm{H}$ and ${ }^{11} \mathrm{~B}$ NMR spectroscopies. This strongly implies that in the bulk synthesis of $\mathbf{5}$, a $\left[3,1,2-\mathrm{CoC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}\right]^{-}$species is formed first (as would be expected from the reaction between a $\{\mathrm{CoCp}\}^{+}$cation and a $\left[7,8-\mathrm{C}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}\right]^{2-}$ anion) and that this 19 e anionic intermediate then isomerises before it is oxidised. Taken together with the facile isomerisation of the $3,1,2-\mathrm{RuC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10} \quad p$-cymene species 2 these observations highlight that the basicity of the metal fragment, and not just its steric bulk, might be important in effecting a $3,1,2-\mathrm{MC}_{2} \mathrm{~B}_{9}$ to $2,1,8-\mathrm{MC}_{2} \mathrm{~B}_{9}$ isomerisation.

For compounds 2, $\mathbf{4}$ and $\mathbf{5}$ we attempted to identify which ${ }^{11} \mathrm{~B}$ resonances were due to which part of the molecule $\left(\left\{\mathrm{MC}_{2} \mathrm{~B}_{9}\right\}\right.$ or $\left.\left\{\mathrm{C}_{2} \mathrm{~B}_{10}\right\}\right)$ from ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}-{ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ COSY spectra but, as was the case with $[\mathbf{1}]^{-}$, it proved impossible to do this unambiguously. In Table 1 we list the weighted average ${ }^{11} \mathrm{~B}$ chemical shifts, $\left\langle\delta\left({ }^{11} \mathrm{~B}\right)\right\rangle$, of the conjoined species $1,1^{\prime}$-bis $(o-$ carborane), $\mathbf{2}, \mathbf{4}$ and $\mathbf{5}$ along with those of their "components", $\left[1,2\right.$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}\right],{ }^{20}[3-(p-$ cymene)-3,1,2-closo- $\left.\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right],{ }^{26}\left[3-\mathrm{Cp}-3,1,2\right.$-closo- $\left.-\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]{ }^{23}$ and [2-Cp-2,1,8-closo$\left.\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right] .{ }^{25}$ Although the spectra of $1,1^{\prime}$-bis $(o \text {-carborane })^{3,6}$ and all these "components" have been reported previously we have remeasured some of them here in $\mathrm{CDCl}_{3}$ for internal consistency. Note that we have not included compound $\mathbf{3}$ in this Table since its $\left\{\mathrm{MC}_{2} \mathrm{~B}_{9}\right\}$ component, [2-(p-cymene)-2,1,8-closo- $\left.\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$, is not currently known.
<Table 1 near here>
These data show that when $1,1^{\prime}$-bis ( $o$-carborane) and the metallacarborane-carborane species 2, $\mathbf{4}$ and $\mathbf{5}$ are "constructed" from their constituent parts the $\left\langle\delta\left({ }^{11} \mathrm{~B}\right)\right\rangle$ value for the "product" lies to high frequency of the (weighted) average of that of the two "components". For 5 the $\left\langle\delta\left({ }^{11} \mathrm{~B}\right)\right\rangle$ value is very close (and slightly to low frequency of) to that for ther metallacarborane component, whilst for $1,1^{\prime}$-bis(o-carborane), $\mathbf{2}$ and $\mathbf{4}$ the $\left\langle\delta\left({ }^{11} \mathrm{~B}\right)>\right.$ value is actually to high frequency of that of both components.

A shift to higher frequency of the average ${ }^{11} \mathrm{~B}$ resonance implies, overall, that the B nuclei in these last two conjoined cages are deshielded, and therefore $\delta+$, relative to those in the individual components. A comparative computational study of $\left[1,2\right.$-closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}\right]$ and $1,1^{\prime}-$
bis( $o$-carborane) supports this conclusion. By DFT calculation we find effectively no preference in $1,1^{\prime}$-bis(o-carborane) between conformations with $\mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 1^{\prime}-\mathrm{C} 2^{\prime}$ torsion angles of $108^{\circ}$ and $180^{\circ}$ (Fig. 2). In terms of only the electronic energy the $108^{\circ}$ conformation is favoured by $0.2 \mathrm{kcal} \mathrm{mol}^{-1}$, whereas if zero point energy is included the $180^{\circ}$ conformation is preferred by $0.5 \mathrm{kcal} \mathrm{mol}^{-1}$. The barrier to free rotation about the $\mathrm{C} 1-\mathrm{C} 1^{\prime}$ bond is only ca. $10 \mathrm{kcal} \mathrm{mol}^{-1}$, corresponding to a transition state at a $\mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 1^{\prime}-\mathrm{C}^{\prime}$ torsion angle of $0^{\circ}$. Computational models are listed in the ESI. It is very satisfying to note that our recent definitive crystallographic study of $1,1^{\prime}$-bis(o-carborane) found that the non-linking C atom is equally disordered between vertices 2 and 3 (and, by symmetry, $2^{\prime}$ and $3^{\prime}$ ). ${ }^{1}$ This means that in the crystal any one molecule of $1,1^{\prime}$-bis( $o$-carborane) is equally likely to have a $\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{C}$ torsion angle of $180^{\circ}\left(\mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 1^{\prime}-\mathrm{C} 2^{\prime}\right)$ or $108^{\circ}\left(\mathrm{C} 3-\mathrm{C} 1-\mathrm{C} 1^{\prime}-\mathrm{C} 2^{\prime}\right)$, in perfect agreement with the results of the DFT study. The computed C1-C1' distance in the $180^{\circ}$ conformation is $1.542 \AA$, and in the $108^{\circ}$ conformation it is $1.540 \AA$. Experimentally C1-C1' is $1.5339(11) ~ \AA .{ }^{1}$

## <Fig. 2 near here>

In Table 2 we list the natural charges for atoms in [1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$ ] and $1,1^{\prime}$-bis $(o-$ carborane), the latter in the $180^{\circ}$ conformation. In [1,2-closo $-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$ ] the C atoms carry a charge of -0.56 and the B atoms an average charge of -0.06 . H bonded to C is +0.36 whilst the average charge of H bonded to B is +0.10 . In $1,1^{\prime}$-bis $(o$-carborane) the negative charge on both C atoms decreases $(\mathrm{C} 1$, the substituted atom, $-0.31 ; \mathrm{C} 2,-0.51)$ and the B atoms are also less negative (average charge -0.04 ). The remaining C -bonded H atom carries a charge of +0.32 and the average charge on H bound to B is +0.09 . Thus substitution of one of the $\mathrm{C}-$ bound H atoms in $\left[1,2\right.$-closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}\right]$ by a $\left\{1^{\prime}, 2^{\prime}\right.$-closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right\}$ unit causes all the polyhedral atoms (both C and B ) in the original cage to become less negatively charged. At the same time there is an opposite, but smaller, change in the charges on the H atoms bonded to the polyhedral atoms, which become slightly less positively charged. The overall charge on the $\left\{\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right\}$ fragment changes from -0.36 in [1,2-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$ ] to precisely zero in $1,1^{\prime}$-bis $\left(o\right.$-carborane). ${ }^{27}$ In brief the $\left\{1^{\prime}, 2^{\prime}\right.$-closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right\}$ substituent is electronwithdrawing compared to H . This conclusion is consistent with our analysis of the $\left\langle\delta\left({ }^{11} \mathrm{~B}\right)\right\rangle$ values for $1,1^{\prime}-\operatorname{bis}(o$-carborane) and for $\mathbf{2}$.
<Table 2 near here>
Salt [BTMA][1] and compounds 2-5 were also studied crystallographically. In [BTMA][1] (Fig. 3) the $\mathrm{C}_{2} \mathrm{~B}_{10}$ cage is ordered but the $\mathrm{C}_{2} \mathrm{~B}_{9}$ cage is disordered with positions 3 and 12 partially occupied by boron. The second C atom of the nido cage is ordered, however, and the $\mathrm{C} 8-\mathrm{C} 7-\mathrm{C} 1^{\prime}-\mathrm{C} 2^{\prime}$ torsion angle is $177.2(6)^{\circ}$. The linking $\mathrm{C} 7-\mathrm{C} 1^{\prime}$ bond length is $1.514(9) \AA$.
<Fig. 3 near here>
Perspective views of single molecules of the $3,1,2-\mathrm{RuC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ species 2, its $2,1,8-$ $\mathrm{RuC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ analogue 3 , and the equivalent cobalt species 4 and 5 are presented in Figs. 4-7, respectively. Since compounds 2, 4 and 5 are composed of $\left\{3,1,2-\right.$ closo $\left.-\mathrm{RuC}_{2} \mathrm{~B}_{9}\right\}$ (compound 2), $\left\{3,1,2\right.$-closo- $\left.-\mathrm{CoC}_{2} \mathrm{~B}_{9}\right\}$ (compound 4) and $\left\{2,1,8-\right.$ closo- $\left.\mathrm{CoC}_{2} \mathrm{~B}_{9}\right\}$ (compound 5) icosahedra conjoined to $\left\{1,2-\right.$ closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10}\right\}$ icosahedra, and all these individual components have previously been studied crystallographically, we have used the Structure Overlay tool in Mercury ${ }^{28}$ to calculate individual atom and overall fragment root-mean-square (rms) misfits between the components of $\mathbf{2 , 4}$ and 5 and the corresponding literature molecules (there is currently no structural study of a 2 -(arene)- $2,1,8$-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}$ species in the literature and so a similar exercise cannot be undertaken for compound $\mathbf{3}$ ). The results, summarised in Table 3, clearly show that for the $\left\{3,1,2-\mathrm{MC}_{2} \mathrm{~B}_{9}\right\}$ fragments the greatest misfit is at the metal vertex, ca. 0.08-0.09 $\AA$, and that the misfit at C 1 (the position of substitution) is also relatively large, ca. 0.06-0.08 A. The overall misfit for $\left\{3,1,2-\mathrm{MC}_{2} \mathrm{~B}_{9}\right\}$ is typically $0.038-0.040 \AA$. In contrast the misfit for the $\left\{2,1,8-\mathrm{MC}_{2} \mathrm{~B}_{9}\right\}$ fragment is considerably less with an overall misfit of only $0.012 \AA$, the greatest individual misfit, $0.025 \AA$, occurring at C 8 (the position of substitution) and no other atom having a misfit $>0.018 \AA$. The $\left\{\mathrm{C}_{2} \mathrm{~B}_{10}\right\}$ fragments fit better with their reference molecule, the overall misfit here being 0.02-0.03 $\AA$, and it is always $\mathrm{C} 1^{\prime}$ or C 2 ' that has the largest individual misfit, typically $0.05-0.06 \AA$.
<Figs. 4-7 near here>
<Table 3 near here>
It is clear from Figs 4 and 6 that a consistent feature of the $3,1,2-\mathrm{MC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ structures is a pronounced bend-back of the arene or Cp ligand in a direction away from the $C_{2} B_{10}$ substituent on $C 1$. This structural feature is undoubtedly the result of intramolecular steric crowding, which also likely contributes to the relatively large misfit values of the metal atoms in 2 and 4. The ligand bend-back is conveniently quantified by $\theta$, the dihedral angle between the plane of the ligand C atoms (arene or Cp ) and the plane defined by B5B6B11B12B9 (the lower pentagonal belt usually taken as the reference plane in 3,1,2$\mathrm{MC}_{2} \mathrm{~B}_{9}$ icosahedra). ${ }^{29}$ For $2 \theta$ is $16.08(9)^{\circ}$ whilst for $4 \theta$ is $15.83(8)^{\circ}$ (molecule A-B) and $16.34(8)^{\circ}$ (molecule C-D; in $\mathbf{4}$ there are two crystallographically-independent molecules A-B and $\mathbf{C}-\mathbf{D}$ where the first letter refers to the $\mathrm{CoC}_{2} \mathrm{~B}_{9}$ cage and second letter to the $\mathrm{C}_{2} \mathrm{~B}_{10}$ cage). C1-C1' distances in 2 and $\mathbf{4}$ are 1.545(3), 1.549(2) (A-B) and 1.550(2) $\AA$ (C-D), respectively. All these are significantly longer that the $\mathrm{C} 1-\mathrm{Cl}^{\prime}$ distance in $1,1^{\prime}$-bis(o-carborane), $1.5339(11) \AA,{ }^{1}$ again a reflection of the steric crowding in 2 and 4.

In the $2,1,8-\mathrm{MC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ compounds 3 and 5 significant intramolecular steric crowding is removed since the $C_{2} B_{10}$ substituent to the $\mathrm{MC}_{2} \mathrm{~B}_{9}$ cage is now at position 8 and
so not adjacent to the metal atom. Consequently the arene or Cp ring plane lies effectively parallel to the lower pentagonal belt, now the C8B4B5B10B12 plane [ $\theta$ is only $0.27(5)^{\circ}$ in 3 and $2.19(7)^{\circ}$ in 5], and the $\mathrm{C} 8-\mathrm{C} 1^{\prime}$ distances are $1.5294(17)$ and $1.5329(16) \AA$, respectively, slightly shorter than or identical to the intercage $\mathrm{C}-\mathrm{C}$ distance in $1,1^{\prime}$-bis(o-carborane). ${ }^{1}$

The gross similarities between the structures of 2 and 4 (similar ligand bend-back angles, similar $\mathrm{C}-\mathrm{C} 1^{\prime}$ distances) imply that, to a first approximation, they are equally sterically crowded. However, whilst 2 is relatively easily isomerised to $\mathbf{3}$ by gentle heating, even prolonged heating to reflux of $\mathbf{4}$ in toluene does not convert it into 5; rather $\mathbf{4}$ has to be reduced to the anion [4] which then isomerises (presumably to [5] ${ }^{-}$) at room temperature, affording 5 on aerial oxidation. This reduction-induced isomerisation of metallacarboranes has precedent in the literature. ${ }^{30}$ Thus, as already has been noted, it appears that the basicity of the metal fragment, and not simply the steric crowding it affords, is important in determining the ease of $3,1,2-\mathrm{MC}_{2} \mathrm{~B}_{9}$ to $2,1,8-\mathrm{MC}_{2} \mathrm{~B}_{9}$ isomerisation in these species. Given that it is generally accepted that cobaltacarboranes are more susceptible to isomerisation than ruthenacarboranes, at least for 13-vertex species, ${ }^{31}$ this is an interesting observation and one that we will address more fully in future contributions. ${ }^{32}$

## Conclusions

Examples of 12-vertex metallacarborane/carborane compounds, $\mathrm{MC}_{2} \mathrm{~B}_{9}-\mathrm{C}_{2} \mathrm{~B}_{10}$, derived from single deboronation and then metallation of $1,1^{\prime}$-bis(o-carborane), have been prepared and characterised. Both non-isomerised $3,1,2-\mathrm{MC}_{2} \mathrm{~B}_{9}-1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ and isomerised $2,1,8-\mathrm{MC}_{2} \mathrm{~B}_{9}-$ $1^{\prime}, 2^{\prime}-\mathrm{C}_{2} \mathrm{~B}_{10}$ isomers have been isolated. For $\mathrm{M}=\{\mathrm{Ru}(p$-cymene $)\}$ the isomerisation of the former to the latter is effected by gentle heating. In contrast, the non-isomerised form with $M$ $=\{\mathrm{CoCp}\}$ does not isomerise in refluxing toluene but readily isomerises as the result of 1 e reduction followed by reoxidation.

## Experimental

## Synthesis

Experiments were performed under dry, oxygen free $\mathrm{N}_{2}$, using standard Schlenk techniques, although subsequent manipulations were sometimes performed in the open laboratory. All solvents were freshly distilled under nitrogen from the appropriate drying agents immediately before use $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}[\mathrm{DCM}], \mathrm{CaH}_{2}\right.$ : THF and $40-60$ petroleum ether; sodium wire) or were stored over $4 \AA$ molecular sieves and were degassed ( $3 \times$ freeze-pump-thaw cycles) before use. Preparative TLC employed $20 \times 20 \mathrm{~cm}$ Kieselgel $\mathrm{F}_{254}$ glass plates. NMR spectra at 400.1 MHz $\left({ }^{1} \mathrm{H}\right)$ or $128.4 \mathrm{MHz}\left({ }^{11} \mathrm{~B}\right)$ were recorded on a Bruker DPX-400 spectrometer from $\mathrm{CDCl}_{3}$ or $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}$ solutions at room temperature. Electron impact mass spectrometry (EIMS) was carried out using a Finnigan (Thermo) LCQ Classic ion trap mass spectrometer at the University of Edinburgh. Elemental analyses were conducted using an Exeter CE-440 elemental analyser at Heriot-Watt University. The starting materials $1,1^{\prime}$-bis( $o$-carborane), ${ }^{6}$ $\left[\mathrm{Ru}(p \text {-cymene }) \mathrm{Cl}_{2}\right]_{2}{ }^{33}\left[\mathrm{Ru}\left(\eta-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Cl}_{2}\right]_{2}{ }^{34}$ and $\mathrm{CpCo}(\mathrm{CO}) \mathrm{I}_{2}{ }^{35}$ were prepared by literature methods or slight variations thereof. All other reagents were supplied commercially.
[ $\mathrm{HNMe}_{3}$ ][7-( $\mathbf{1}^{\prime}-\mathbf{1}^{\prime}, \mathbf{2}^{\prime}$-closo- $\left.\mathrm{C}_{2} \mathbf{B}_{10} \mathrm{H}_{11}\right)$-7,8-nido- $\left.\mathrm{C}_{2} \mathbf{B}_{9} \mathbf{H}_{11}\right]$ ([HNMe $\left.{ }_{3}\right][1]$ ) and [BTMA][7-(1'-1', 2'-closo- $\mathbf{C}_{2} \mathbf{B}_{10} \mathbf{H}_{11}$ )-7,8-nido- $\left.\mathbf{C}_{2} \mathbf{B}_{9} \mathbf{H}_{11}\right]$ ([BTMA][1]). 1,1'-bis $(o$-carborane $(0.50 \mathrm{~g}$, $1.75 \mathrm{mmol})$ and $\mathrm{KOH}(0.09 \mathrm{~g}, 1.75 \mathrm{mmol})$ were heated to reflux in $\mathrm{EtOH}(30 \mathrm{~mL})$ for 4 hr . The solution was allowed to cool and the solvent removed to give a white oily residue. Deionised water ( 20 mL ) was added, and the suspension filtered to give a slightly cloudy solution. To this was added an aqueous solution of either $\left[\mathrm{HNMe}_{3}\right] \mathrm{Cl}(0.17 \mathrm{~g}, 1.8 \mathrm{mmol})$ or [BTMA]Cl $(0.32 \mathrm{~g}, 1.8 \mathrm{mmol})$ resulting in the immediate precipitation of $\left[\mathrm{HNMe}_{3}\right]\left[7-\left(1^{\prime}-\right.\right.$ $1^{\prime}, 2^{\prime}-$ closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-7,8$-nido- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ ([HNMe 3$][1]$ ) or [BTMA][7-(1'-1',2'-closo$\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-7,8$-nido- $\left.\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]$ ([BTMA][1]) as white solids. These were isolated by filtration, washed with $\mathrm{H}_{2} \mathrm{O}(3 \times 20 \mathrm{~mL})$ and dried in vacuo.
[ $\mathrm{HNMe}_{3}$ ][1]: Yield $0.37 \mathrm{~g}, 64 \% . \mathrm{C}_{7} \mathrm{H}_{32} \mathrm{~B}_{19} \mathrm{~N}$ requires $\mathrm{C} 25.0, \mathrm{H} 9.60, \mathrm{~N} 4.17$. Found for [ $\mathrm{HNMe}_{3}$ ]1: C 24.7, H 9.71, N 4.04\%. ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}\right], \delta-3.9$ (1B), -6.0 (1B), -8.8 (1B), -10.4 (5B), -11.2 (sh., 2B), -13.5 (3B), -16.8 (2B), -19.0 (1B), -22.7 (1B), -33.9 (1B), -35.3 (1B). ${ }^{1} \mathrm{H}$ NMR $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}\right], \delta 4.36\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{C} H_{\text {cage }}\right), 3.22\left(\mathrm{~s}, 9 \mathrm{H}, \mathrm{N}\left(\mathrm{CH}_{3}\right)_{3}\right), 1.99(\mathrm{~s}, 1 \mathrm{H}$, $\mathrm{C} H_{\text {cage }}$ ).
[BTMA][1]: Yield $0.55 \mathrm{~g}, 74 \% . \mathrm{C}_{14} \mathrm{H}_{38} \mathrm{~B}_{19} \mathrm{~N}$ requires $\mathrm{C} 39.5, \mathrm{H} 8.99, \mathrm{~N} 3.29$. [1-(1'-1', 2'-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$-3-(p-cymene)-3,1,2-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (2) and [8-(1'-1', $2^{\prime}$ -closo- $\mathbf{C}_{2} \mathbf{B}_{10} \mathbf{H}_{11}$ )-8-(p-cymene)-2,1,8-closo- $\mathrm{RuC}_{2} \mathbf{B}_{\mathbf{9}} \mathbf{H}_{10}$ ] (3). $n$ - $\mathrm{BuLi}(0.48 \mathrm{~mL}$ of 2.5 M solution, 1.2 mmol ) was added dropwise to a cooled $\left(0^{\circ} \mathrm{C}\right)$ solution of $\left[\mathrm{HNMe}_{3}\right][\mathbf{1}](0.20 \mathrm{~g}$, $0.60 \mathrm{mmol})$ in THF $(20 \mathrm{~mL})$ and the products stirred for 1 hr . The pale yellow solution was frozen at $-196{ }^{\circ} \mathrm{C},\left[\mathrm{RuCl}_{2}(p \text {-cymene })\right]_{2}(0.18 \mathrm{~g}, 0.30 \mathrm{mmol})$ added and the reaction mixture stirred overnight at room temperature. THF was removed in vacuo and the crude mixture dissolved in DCM and filtered through Celite ${ }^{\circledR}$. Preparative TLC using an eluent system of DCM and petroleum ether in a ratio of $30: 70$ afforded a yellow band ( $R_{\mathrm{f}}=0.47$ ) subsequently identified as [1-( $1^{\prime}-1^{\prime}, 2^{\prime}$-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)$-3-(p-cymene)-3,1,2-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (2) (0.024 g, $8 \%)$ and a colourless band $\left(R_{\mathrm{f}}=0.51\right)$ identified as $\left[8-\left(1^{\prime}-1^{\prime}, 2^{\prime}-\right.\right.$ closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-2-(p-$ cymene)-2,1,8-closo- $\mathrm{RuC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (3) ( $0.057 \mathrm{~g}, 19 \%$ ).

2: $\mathrm{C}_{14} \mathrm{H}_{35} \mathrm{~B}_{19} \mathrm{Ru}$ requires C 33.0, H 6.92. Found for 2: C 32.5, H 7.17\%. ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left[\mathrm{CDCl}_{3}\right], \delta 2.8(1 \mathrm{~B}), 0.5(1 \mathrm{~B}),-2.8(2 \mathrm{~B}),-3.9$ (sh., 1B), -7.2 (2B), $-8.8(2 \mathrm{~B}),-10.7$ (4B), 12.6 (2B), -14.4 (1B), -17.2 (3B). ${ }^{1} \mathrm{H}$ NMR $\left[\mathrm{CDCl}_{3}\right], \delta 6.11-5.96\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{C}_{6} H_{4}\right), 4.03(\mathrm{~s}, 1 \mathrm{H}$, $\mathrm{CH}_{\text {cage }}$ ), $3.91\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CH} \mathrm{cage}\right.$ ), 3.04 (app. septet, $\left.1 \mathrm{H}, \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 2.49\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3}\right), 1.37(\mathrm{~d}, 3 \mathrm{H}$, $\left.\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right)$, $1.35\left(\mathrm{~d}, 3 \mathrm{H}, \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right)$. EIMS: envelope centred on $m / z 510\left(\mathrm{M}^{+}\right)$.

3: $\mathrm{C}_{14} \mathrm{H}_{35} \mathrm{~B}_{19} \mathrm{Ru}$ requires C 33.0, H 6.92. Found for 3: C 33.0, H 6.82\%. ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left[\mathrm{CDCl}_{3}\right], \delta-1.0(2 \mathrm{~B}),-2.8(2 \mathrm{~B}),-4.1(1 \mathrm{~B}),-4.9(2 \mathrm{~B}),-8.0(1 \mathrm{~B}),-10.1(6 \mathrm{~B}),-13.4(2 \mathrm{~B}),-16.2$ (1B), -19.2 (1B), -20.4 (1B). ${ }^{1} \mathrm{H}$ NMR $\left[\mathrm{CDCl}_{3}\right], \delta 5.94-5.84\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{C}_{6} H_{4}\right), 3.64(\mathrm{~s}, 1 \mathrm{H}$, $\mathrm{C} H_{\text {cage }}$ ), 2.81 (app. septet, $\left.1 \mathrm{H}, \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 2.63\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{C} H_{\text {cage }}\right), 2.31\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH} H_{3}\right), 1.30(\mathrm{~d}, 3 \mathrm{H}$, $\left.\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.28\left(\mathrm{~d}, 3 \mathrm{H}, \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right)$. EIMS: envelope centred on $m / z 510\left(\mathrm{M}^{+}\right)$.

Thermal isomerisation of 2. Compound $2(0.024 \mathrm{~g}, 0.05 \mathrm{mmol})$ was dissolved in THF $(20 \mathrm{~mL})$ and the solution heated at reflux for 2 hr . The solvent was removed and the product purified by preparative TLC using an eluent system of DCM:petroleum ether, 30:70, to afford a colourless band at $R_{\mathrm{f}}=0.51$ identified as $3(0.014 \mathrm{~g}, 58 \%)$ by ${ }^{1} \mathrm{H}$ and ${ }^{11} \mathrm{~B}$ NMR spectroscopies.
[1-(1'-1', 2'-closo- $\mathbf{C}_{\mathbf{2}} \mathbf{B}_{\mathbf{1 0}} \mathbf{H}_{\mathbf{1 1}}$ )-3-Cp-3,1,2-closo- $\mathrm{CoC}_{\mathbf{2}} \mathbf{B}_{\mathbf{9}} \mathbf{H}_{\mathbf{1 0}}$ ] (4). [HNMe $\left.{ }_{3}\right][\mathbf{1}](0.25 \mathrm{~g}, 0.74$ mmol) was deprotonated with $n-\mathrm{BuLi}(0.60 \mathrm{~mL}$ of 2.5 M solution, 1.48 mmol$)$ as above then frozen at $-196{ }^{\circ} \mathrm{C}$. To this was added $\mathrm{CpCo}(\mathrm{CO}) \mathrm{I}_{2}(0.30 \mathrm{~g}, 0.74 \mathrm{mmol})$ and the reaction mixture was allowed to warm to room temperature and stirred overnight. Following spot TLC* (DCM:petroleum ether, $30: 70, R_{\mathrm{f}}=0.28$ ) purification by column chromatography using the same eluent gave, on removal of solvent, an orange powder $(0.038 \mathrm{~g}, 13 \%)$, subsequently identified as [1-(1'-1', 2'-closo- $\left.\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-3-\mathrm{Cp}-3,1,2$-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (4). $\mathrm{C}_{9} \mathrm{H}_{26} \mathrm{~B}_{19} \mathrm{Co}$ requires $\mathrm{C} 27.1, \mathrm{H} 6.57$. Found for 4: C $26.5, \mathrm{H} 6.67 \%$ 。 ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left[\mathrm{CDCl}_{3}\right], \delta 6.5$ (1B), $2.5(1 \mathrm{~B}),-2.6(5 \mathrm{~B}),-4.4(1 \mathrm{~B}),-8.0(2 \mathrm{~B}),-9.7(5 \mathrm{~B}),-12.3(2 \mathrm{~B}),-14.2(1 \mathrm{~B}),-15.9(1 \mathrm{~B}) .{ }^{1} \mathrm{H}$

NMR $\left[\mathrm{CDCl}_{3}\right], \delta 5.86\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 4.24\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{C} H_{\text {cage }}\right), 4.03\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{C} H_{\text {cage }}\right)$. EIMS: envelope centred on $m / z 399\left(\mathrm{M}^{+}\right)$.

* A trace amount of a yellow spot $\left(R_{\mathrm{f}}=0.34\right)$ identified as $\left[8-\left(1^{\prime}-1^{\prime}, 2^{\prime}-\right.\right.$ closo $\left.-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}\right)-2-\mathrm{Cp}-$ 2,1,8-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (5) was also observed and its identity confirmed via ${ }^{1} \mathrm{H}$ NMR spectroscopy.
[8-(1'-1',2'-closo- $\left.\mathbf{C}_{2} \mathbf{B}_{10} \mathbf{H}_{11}\right)$-2-Cp-2,1,8-closo- $\mathrm{CoC}_{\mathbf{2}} \mathrm{B}_{\mathbf{9}} \mathbf{H}_{\mathbf{1 0}}$ ] (5). [HNMe $\left.{ }_{3}\right][1](0.20 \mathrm{~g}, 0.60$ mmol) was deprotonated with $n-\mathrm{BuLi}(0.48 \mathrm{~mL}$ of 2.5 M solution, 1.20 mmol$)$ as above and frozen at $-196{ }^{\circ} \mathrm{C}$. To this were added $\mathrm{NaCp}(0.89 \mathrm{~mL}$ of 2.0 M solution, 1.79 mmol$)$ and $\mathrm{CoCl}_{2}(0.28 \mathrm{~g}, 2.20 \mathrm{mmol})$ added and the mixture stirred overnight at room temperature. Following aerial oxidation ( 0.5 hr ) and filtration through silica THF was replaced by DCM and the product again filtered, through Celite ${ }^{\circledR}$. Following spot TLC** (DCM:petroleum ether, $\left.50: 50, R_{\mathrm{f}}=0.69\right)$ purification by column chromatography using the same eluent gave, on removal of solvent, a yellow powder ( $0.117 \mathrm{~g}, 49 \%$ ), subsequently identified as [8-(1'$1^{\prime}, 2^{\prime}$-closo- $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{11}$ )-2-Cp-2,1,8-closo- $\mathrm{CoC}_{2} \mathrm{~B}_{9} \mathrm{H}_{10}$ ] (5). $\mathrm{C}_{9} \mathrm{H}_{26} \mathrm{~B}_{19}$ Co requires C 27.1, H 6.57. Found for 6: C 27.1, H 6.75\%。 ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left[\mathrm{CDCl}_{3}\right], \delta 1.7$ (1B), 0.0 (2B), -0.9 (1B), -2.5 (1B), -3.8 (1B), -6.1 (2B), -9.9 (6B), -11.8 (1B), -13.2 (2B), -16.8 (1B), -17.7 (1B). ${ }^{1} \mathrm{H}$ NMR $\left[\mathrm{CDCl}_{3}\right], \delta 5.50\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} H_{5}\right), 3.59\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{C} H_{\text {cage }}\right), 2.73\left(\mathrm{~s}, 1 \mathrm{H}, \mathrm{C} H_{\text {cage }}\right)$. EIMS: envelope centred on $m / z 399\left(\mathrm{M}^{+}\right)$.
** A trace amount of an orange spot $\left(R_{\mathrm{f}}=0.60\right)$ identified as 4 was also observed and its identity confirmed via ${ }^{1} \mathrm{H}$ NMR spectroscopy.

Attempted thermal isomerisation of 4. Compound $4(0.038 \mathrm{~g}, 0.10 \mathrm{mmol})$ was dissolved in toluene ( 20 mL ) and the solution heated at reflux for 5 hr . The solvent was removed and the crude residue was submitted for ${ }^{1} \mathrm{H}$ and ${ }^{11} \mathrm{~B}$ NMR spectroscopies, however there was no evidence that $\mathbf{4}$ had converted to 5. Preparative TLC using an eluent of DCM: petroleum ether, $30: 70$, led to the recovery of $4(0.020 \mathrm{~g}, 53 \%)$.

Redox isomerisation of 4. To a solution of $4(0.012 \mathrm{~g}, 0.030 \mathrm{mmol})$ in dry degassed THF $(10 \mathrm{~mL})$ was added a solution of sodium naphthalenide $(1 \mathrm{~mL}$ of a 0.031 M solution in THF, 0.031 mmol ). The reaction was allowed to stir under nitrogen for 1 hr , oxidised using a water aspirator for 30 min , and solvent was removed in vacuo. Only compound 5 was identified by ${ }^{1} \mathrm{H}$ and ${ }^{11} \mathrm{~B}$ NMR spectroscopies.

## Crystallography

Diffraction-quality crystals of salt [BTMA][1] and compounds 2, 3, $\mathbf{4}$ and $\mathbf{5}$ were afforded by slow diffusion of a $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution of the appropriatre species and $40-60$ petroleum ether at $-30^{\circ} \mathrm{C}$. Intensity data for all except 4 were collected on a Bruker X8 APEXII diffractometer using $\mathrm{Mo}-\mathrm{K}_{\alpha} X$-radiation, with crystals mounted in inert oil on a cryoloop and cooled to 100 K by an Oxford Cryosystems Cryostream. Compound 4 afforded crystals too small for our
in-house system and consequently data were collected at the National Crystallographic Service at the University of Southampton at 100 K on a Rigaku AFC12 diffractometer operating with $\mathrm{Mo}-\mathrm{K}_{\alpha} X$-radiation. Indexing, data collection and absorption correction were performed using the APEXII suite of programs. ${ }^{36}$ Structures were solved by direct methods (SHELXS ${ }^{37}$ or OLEX2 ${ }^{38}$ ) and refined by full-matrix least-squares (SHELXL). ${ }^{37}$

Cage C atoms not involved in the intercage link were identified by a combination of (i) the examination of refined (as B) isotropic thermal parameters, (ii) the lengths of cage connectivities, (iii) the Vertex-Centroid Distance Method ${ }^{39}$ and (iv) the Boron-H Distance Method, ${ }^{40}$ with all four methods affording excellent mutual agreement.

The anion in [BTMA][1] is partially disordered. The $\mathrm{C}_{2} \mathrm{~B}_{10}$ cage is fully ordered but the $\mathrm{C}_{2} \mathrm{~B}_{9}$ cage has one B atom disordered between two sites, B 3 and B 12 , with SOFs 0.548 (10) and $0.452(10)$ respectively. Atoms B 3 and B 12 were refined with an isotropic thermal parameter fixed at $0.03 \AA^{2}$. There is also partial disorder in 3 between atoms $\mathrm{C}^{\prime}$ and $\mathrm{B}^{\prime}$ $\left(\mathrm{C}_{2} \mathrm{~B}_{10}\right.$ cage $)$, successfully modelled with vertex 2 being $0.446(19) \mathrm{C}+0.554(19) \mathrm{B}$, with complementary SOFs at vertex 3 .

In [BTMA][1] it was not possible to locate the (disordered) bridging H atom associated with the open face of the nido cage and final refinement with constrained BH and $\mathrm{C}_{\text {cage }} \mathrm{H}$ atoms $\left(\mathrm{B}-\mathrm{H}=\mathrm{C}_{\text {cage }}-\mathrm{H}=1.12 \AA\right)$ afforded better agreement than that with these H atoms allowed to refine. In the BTMA cation the H atoms were constrained to $\mathrm{C}_{\text {phenyl }}-\mathrm{H}=0.95 \AA$, $\mathrm{C}_{\text {secondary }}-\mathrm{H}=0.99 \AA, \mathrm{C}_{\text {methyl }}-\mathrm{H}=0.98 \AA$. For all other structures BH and $\mathrm{C}_{\text {cage }} \mathrm{H}$ atoms were allowed to refine positionally whilst other H atoms were constrained to idealised geometries; $\mathrm{C}_{\text {aromatic }}-\mathrm{H}=1.00 \AA, \mathrm{C}_{\mathrm{Cp}}-\mathrm{H}=1.00 \AA, \mathrm{C}_{\text {tertiary }}-\mathrm{H}=1.00 \AA, \mathrm{C}_{\text {methyl }}-\mathrm{H}=0.98 \AA$. All H displacement parameters, $U_{\text {iso }}$, were constrained to be $1.2 \times U_{\text {eq }}$ (bound B or C) except Me H atoms $\left[U_{\text {iso }}(\mathrm{H})=1.5 \times U_{\text {eq }} \mathrm{C}(\mathrm{Me})\right]$. Table 4 contains further experimental details. <Table 4 near here>

## Calculations

All geometries were optimised without constraints using Gaussian 03, Revision D. $01{ }^{41}$ employing the BP86 functional ${ }^{42}$ and $6-31 \mathrm{G}^{* *}$ basis sets for $\mathrm{B}, \mathrm{C}$ and H atoms. ${ }^{43}$ Analytical frequency calculations were used to confirm geometries as minima or transition states. The transition state was further characterised through IRC calculations. ${ }^{44}$

Fig. $1 \quad 1,1^{\prime}$-bis(o-carborane).

Fig. 2 Plot of energy vs. dihedral angle for 1,1'-bis(o-carborane) from DFT calculation where the $\mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 1^{\prime}-\mathrm{C} 2^{\prime}$ torsion angle was subjected to a relaxed scan from $-180^{\circ}$ to $0^{\circ}$ and the resulting data points mirrored to illustrate full $360^{\circ}$ rotation.

Fig. 3 Perspective view of the anion in the salt [BTMA][1] and atom numbering scheme. In the unprimed cage there is partial disorder of B3, part of which appears as the $12^{\text {th }}$ atom of an icosahedron (not shown for clarity); partial occupancies are B3 0.548(10) and B12 0.452(10). The H atom bridging on the open face of the unprimed cage was not located. Displacement ellipsoids are drawn at the $40 \%$ probability level except for H atoms.

Fig. 4 Perspective view of compound 2 and atom numbering scheme. Displacement ellipsoids are drawn at the $50 \%$ probability level except for H atoms.

Fig. 5 Perspective view of compound 3 and atom numbering scheme. Position $2^{\prime}$ is $0.446(19) \mathrm{B}+0.554(19) \mathrm{C}$, with complementary occupations at position $3^{\prime}$. Displacement ellipsoids as for Fig. 4.

27 Since 1, $1^{\prime}$-bis (o-carborane) is neutral overall and symmetric about the $\mathrm{C} 1-\mathrm{C} 1^{\prime}$ mid-point, the two halves individually must be neutral.

Singly-metallated derivatives of $1,1^{\prime}$-bis(o-carborane) with both $\{\mathrm{Ru}$ (arene) $\}$ and $\{\mathrm{CoCp}\}$ fragments have been prepared and characterised; with $\{\mathrm{Ru}(\mathrm{p}-\mathrm{cymene})\}$ both unisomersied and isomerised species are formed and the former is easily converted to the latter with mild heating, whereas the product obtained with $\{\mathrm{CoCp}\}$ depends upon the source of that fragment and a redox step is required to effect the isomerisation.
