This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

Cycloaddition Reactions of (C₆F₅)₂BN₃ with Dialkyl Acetylenedicarboxylates

Rebecca L. Melenᵃ,ᵇ and Douglas W. Stephan⁴ᵃ *

Received 00th January 2012
Accepted 00th January 2012
DOI: 10.1039/x0xx00000x

The 1,3-dipolar cycloaddition reactions of the electron deficient boron azide, (C₆F₅)₂BN₃ (1) with the electron-poor acetylenes RO₂CC==CCO₂R (R = Me, Et) afforded the new mono- and bis-1,2,3-triazole derivatives 5 and 6.

“Click reactions” including the synthesis of 1,2,3-triazoles from the cycloaddition reaction between an azide and an alkyne were first described in 2001 by Kolb, Finn and Sharpless.¹⁻⁵ Such reactions have found broad utility in organic synthesis including pharmaceutical chemistry, polymer synthesis and material science as these reactions are rapid and offer high yields with no waste by-product. Typically Cu or Ru salts are used to catalyse the azide-alkyne cycloaddition.⁶⁻¹¹ Nonetheless, uncatalysed click reactions have been known to be affected at elevated temperatures for over 100 years although such reactions frequently result in mixtures of 1,4- and 1,5-regio-isomers.¹²

Boron azide compounds (R₂BN₃)¹³⁻²⁰ can be readily synthesised from salt elimination reactions of R₂BCl with NaN₃ or the substitution reactions of R₂BCl with Me₂SN₃. Nonetheless, applications of boron azides are relatively scarce. Boron azides have been used as precursors to borylnitrenes,²¹⁻²⁶ and the boron azides R₂BN₃ [R = C₆F₅ (1), Cy (2)] were employed in Staudinger phosphate oxidations affording boron-substituted phosphinimine derivatives.²⁷ More recently, (C₆F₅)₂BN₃ was shown to undergo aromatic C-H activation of benzene and toluene when reacted with boron substituted alkynes.²⁸ In 2012, Curran et al. reported the reactivity of the electron-rich NHCl-boryl azide 3 with electron-deficient alkynes, alkenes and nitriles,²⁹ while Bettinger et al. have reported that although the boryl azide, 2-azido-4,4,5,5-tetramethyl-1,3,2-dioxaborole (pinBN₃, 4)³⁰ reacts with cyclooctyne, it does not react with electron-poor acetylenes such as MeO₂CC==CCO₂Me. Previously we have described the cycloadditions of more electron deficient boron azides with alkynes.²⁷, ³¹⁻³² For example, the boron azide Cy₂BN₃ generated in situ, undergoes catalyst-free cycloadditions generating novel boron-substituted heterocycles.³² The varying reactivity of boron azides with RO₂CC==CCO₂R described to date (Scheme 1) prompted us to probe the room temperature catalyst-free reaction of the electron deficient (C₆F₅)₂BN₃ with dialkyl acetylenedicarboxylates. In this manuscript we show that the reactivity of (C₆F₅)₂BN₃ (Scheme 2) with alkynes is markedly different to that of Cy₂BN₃ (Scheme 1).

Scheme 1 Reactions of boron azides with dialkyl acetylenedicarboxylates.

Scheme 2. Synthesis of 5 and 6.

The boron azide (C₆F₅)₂BN₃ (1) was synthesised in high yield via the method reported by Klapötke in 2000³⁰ from the 1:1 stoichiometric reactions of the chloroborane (C₆F₅)₂BCl¹³ with trimethylsilyl azide. To avoid storage of the potentially explosive boron azide, 1 was prepared and subsequently reacted in situ with electron deficient acetylenes RO₂CC==CCO₂R (R = Me, Et). In the initial case, the room temperature stoichiometric reaction of 1 with MeO₂CC==CCO₂Me over 48h afforded a green solution. Removal of
the solvent resulted in a dark green oil which was recrystallised from a pentane/toluene solution to afford a small crop of large colourless crystals of 5 (Scheme 2). X-ray diffraction confirmed the identity of 5 as a bicyclic system bearing one triazole C₅N₃ ring fused to a B₃N₃ ring (Fig. 1). The triazole ring is essentially planar (max. deviation from planarity 0.002 Å). However the B₃N₃ ring deviates from a planar structure with the azide functionality lying out of the plane (the nitrogen atom bridging the boron atoms lies 0.225 Å from the ring plane) with the azide bent out of the ring plane by 165.1°. Two of the C₆F₅ groups adopt a near coplanar geometry (9.0° from coplanar) with ring centroid···centroid distances of just 3.44 Å, falling at the shorter end of the range observed for other C₆F₅···C₆F₅ π···π contacts (3.23 – 4.7 Å).34 The resulting structure of 5 is comparable to those previously reported from reactions of Cy₂BN₃ with EtC≡CCOMe or Ph₂P(=O)C≡CH which led to the formation of similar fused triazole and B₂N₃ rings.32

It is noteworthy that the boron azide 1 is known to exist in the solid state as a 1,1-azide-bridged dimer with a 4-membered B₂N₂ core.20 Thus it is tempting to suggest that 5 arises from the 1,3-dipolar cycloaddition of one azide fragment of the dimer 1 with the alkyne affording the 1,2,3-triazole fragment. In this fashion the bridging coordination of a second equivalent of azide between the boron centres is maintained. However, [(Cy₆F₅)₂BN₃]₂ is known to dissociate in solution,20 and a reaction pathway involving monomeric (Cy₆F₅)₂BN₃ is more likely and discussed further below.

The corresponding reaction of 1 with EtO₂CC≡CCO₂Et resulted in a dark red solution after stirring for 48h at room temperature. Removal of the solvent led to an oil which could be recrystallised from hexane over several months to give large colourless crystals of 6 (Scheme 2). The structure of 6 was determined by X-ray diffraction (Fig. 2). In contrast to 5, the structure of 6 is comprised of a fused tricyclic system constructed from two 5-membered triazole rings bridged by two boron atoms leading to a central 6-membered N₆B₆ ring. Whilst the triazole rings are planar (max. deviation from planarity 0.004 Å and 0.009 Å) the central ring adopts a boat geometry due to the tetrahedral boron atoms. This has the effect of creating a molecular butterfly-type geometry with the triazole wings inclined by 138.4°

with respect to each other. Notably the two axially-disposed C₆F₅ rings are nearly parallel (7.2°) with a centroid···centroid separation of 3.45 Å, similar to that in 5. It is interesting to note that 6 is not a centrosymmetric triazole dimer, suggesting that the thermodynamically favoured polar dimer is formed on prolonged exposure of the analogue of 5 to alkyne. Both 5 and 6 were fully characterised by NMR, mass spectroscopy and elemental analysis. Multinuclear NMR data for 5 reveal that its structure appears intact in solution as shown by a peak in the ¹¹B NMR spectrum around 0 ppm with no evidence for dissociation at room temperature to regenerate free triazole and (Cy₆F₅)₂BN₃ (δ = 43.9 ppm).20

**Scheme 3** Potential route for the synthesis of 5 and 6.

The chemistry of these boron-azide/triazole systems seems to be determined by the Lewis acidity of the boron centre which affords some degree of aggregation particularly in the solid state structures of these compounds. DFT studies35 (B3LYP/6-311G*) indicate that reaction of the alkyne MeO₂CC≡CCO₂Me and monomeric (Cy₆F₅)₂BN₃ occurs through interaction of the alkyne HOMO with the LUMO of the azide forming the anticipated 5-membered triazole ring, 11 (ΔH = -200 kJ/mol) (see ESI). The Lewis acidity of boron and Lewis basicity of the central nitrogen atom of the triazole ring prompt capture of free (Cy₆F₅)₂BN₃ affording 5 (ΔH = -79 kJ/mol) (Scheme 3).
Whilst formation of 5 appears to occur via a simple two-step process, the mechanism of formation of the polar dimer 6 is less evident. One plausible mechanism involves the dissociation of 5 regenerating \((\text{C}_6\text{F}_5)_2\text{BN}_3\) and intermediate 12, effectively affording a 1,2-migration of the \((\text{C}_6\text{F}_5)_2\) moiety. Calculations reveal this is a low energy transformation (\(\Delta H = +51 \text{kJ/mol}\)). Reaction of 12 with 11 would afford the polar dimer 6′ (Scheme 3) (\(\Delta H = -111 \text{kJ/mol}\)).

The isolation of both 1:1 and 2:1 products based on a 1:1 stoichiometric reaction presumably reflects subtle differences in the stereo-electronics of the reaction chemistry such that the rate constant for formation of compound 6 from intermediates 11 and 12 is comparable with that for formation of 5 from 11 and unreacted \((\text{C}_6\text{F}_5)_2\text{BN}_3\). Both are associated with a Lewis acid-base aggregation process. In addition, the low recovered yields (14% and 22% respectively), the isolation of 1:1 and 2:1 adducts may in part be driven by the relative solubilities of 5 and 6 under differing recrystallisation conditions. This does not preclude other species being present in solution as the isolated products were just the least soluble under the recrystallization conditions employed.

Previously, theoretical studies by Bettinger showed that tricoordinate boron azides act as ambiphilic 1,3-dipoles, whilst electron rich, NHC-stabilised tetracoordinate boron azides react preferentially with electron deficient alkynes. Both \(\text{Cy}_2\text{BN}_3\) and \((\text{C}_6\text{F}_5)_2\text{BN}_3\) act as electron-poor azides but reveal differing reactivity towards acetylenedicarboxylates. In this regard it is also noteworthy that Bettinger found that \(\text{PhBN}_3\) does not react with acetylenedicarboxylates. Thus the unique products 5 and 6 appear to reflect the increased Lewis acidity of the B centre in 1.

Conclusions

In conclusion, the boron azide \((\text{C}_6\text{F}_5)_2\text{BN}_3\) 1 reacts with dialkyl acetylenedicarboxylates to give mono and bis-triazole derivatives 5 and 6. However, whilst these reactions are providing new insights into boron-azole cycloaddition chemistry, the low recovered yields and apparent diversity of reactivity preclude them from being described as conventional azide/alkyne “click reactions”. These products contrast sharply with those derived from known “click” products derived from other boron azides and alkyl acetylenedicarboxylates. The subtly differing reactivity of \((\text{C}_6\text{F}_5)_2\text{BN}_3\) and \(\text{Cy}_2\text{BN}_3\) towards alkyne carboxylates poses questions about the structure-reactivity relationships in these boron azides which can be potentially met through studies of other boron azides, \(\text{R}_2\text{BN}_3\), as well as computational studies. Such efforts will be the subject of future publications.
