This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
A simple methodology for encapsulating ca. 10 nm-sized superparamagnetic \( \text{Fe}_3\text{O}_4 \) nanoparticles in zeolitic imidazolate frameworks (ZIF-8) crystals was developed. The corresponding \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) heterostructured material exhibits bifunctional properties with both high magnetization (\( \text{Fe}_3\text{O}_4 \)) and high thermal stability, large specific surface, and catalytic properties (ZIF-8). The \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) catalyst exhibits fair separation ability and reusability, which can be repeatedly applied for Knoevenagel condensations and Huisgen cycloadditions for at least ten successive cycles.

Among metal organic frameworks (MOFs), zeolitic imidazolate frameworks (ZIFs) are microporous crystalline materials with high thermal and chemical stability which have attracted particular attention for gas storage and gas separation. In ZIF-8 crystals, the network consists of \( \text{Zn}^{2+} \) atoms arranged as of \([\text{ZnN}_4] \) tetrahedrons with the \( \text{N} \) atoms of 2-methylimidazolate (\( \text{mim} \)) linkers. ZIF-8 has a sodalite zeolite-type topology with cages of 11.6 Å and pores of 3.4 Å in diameter. The efficiency of ZIF-8 has been demonstrated in gas separation, gas storage, but also for heterogeneous catalytic transformations (Knoevenagel condensations, cycloadditions, oxidations, trans-esterification, and Friedel-Crafts alkylations).

Nevertheless, one major problem with the reuse of ZIF-8 heterogeneous catalysts remains their separation from the reaction products. Because of the ease of magnetic separation from the reaction mixture, this strategy is more effective than nanofiltration through a membrane or centrifugation in that it allows the catalyst to be recovered. Superparamagnetic particles are intrinsically nonmagnetic but can be readily magnetized in the presence of an external magnetic field. This property enables trouble-free separation of the particles from the reaction medium by simply applying an external magnet, thus eliminating filtration or centrifugation operations. Additionally, magnetic particles exhibit high chemical stability and can be considered as inert in most chemical transformations. Finally, magnetic separation of nanoparticles is economical and promising for industrial applications.

In recent years, a couple of approaches have been developed for the encapsulation of small-sized functional nanoparticles like metal particles (Au, Ag, Pt, Pd, Ni) or quantum dots (CdSe, ZnO, GaN) into MOFs to build hybrid materials for catalytic or optical applications. \( \text{Fe}_3\text{O}_4 \) nanoparticles capped with the \([\eta^5\text{-semiquinone}]\text{Mn(CO)}_3 \) ligand or with polyacrylic acid have successfully been incorporated in organometallic coordination polymers involving \( \text{Mn}^{2+} \), \( \text{Cd}^{2+} \) or \( \text{In}^{3+} \). The MIL-100 MOF (\( \text{Fe}^{3+} \) associated to 1,3,5-benzenetricarboxylate) has recently been grown onto large \( \text{Fe}_3\text{O}_4 \) or \( \text{Fe}_3\text{O}_4/\text{Au} \) particles (200-600 nm) to develop reusable catalysts for Claisen-Schmidt condensations and for the reduction of 4-nitrophenol. A similar approach was also used to deposit small-sized ZIF-8 crystals (70-140 nm) at the outer-surface of \( \text{Fe}_3\text{O}_4 \) crystals (380-600 nm) to prepare core/shell \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) particles without alteration of the properties of both materials. The magnetic properties of these core/shell particles were successfully used for the deposition of catalytically active ZIF-8 material in microreactors or for the development of reusable sorbent particles.

Herein, we report for the first time a simple strategy to spread ca. 10 nm-sized \( \text{Fe}_3\text{O}_4 \) nanoparticles into the cavities and/or channels of ZIF-8 crystals. The porous crystalline \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) particles exhibit high catalytic activity in Knoevenagel condensations and present the advantage of being magnetically recoverable at the end of reactions and reusable for up to ten cycles with no visible deterioration of their catalytic activity. The method was successfully extended to \( \text{Cu}^{2+} \)-doped ZIF-8 and allowed the preparation of recyclable catalysts for Huisgen 1,3-dipolar cycloadditions.

The preparation procedure of \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) particles is schematically illustrated in Fig. 1.
and Hmim were dispersed in water and the mixture stirred for 5 min under inert atmosphere. Next, an aqueous solution of Zn(NO$_3$)$_2$ (molar ratio Hmim/Zn(NO$_3$)$_2$ = 70/1) was added and the resulting mixture was stirred at room temperature for 10 min. Fe$_3$O$_4$@ZIF-8 crystals were separated by using an external magnetic field and purified by washing with water and ethanol. The structure and morphology of Fe$_3$O$_4$@ZIF-8 particles were characterized by powder X-ray diffraction (PXRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), and N$_2$ adsorption at 77K.

As shown by TEM and SEM experiments, ZIF-8 crystals exhibit the well-defined and thermodynamically favorable truncated rhombic dodecahedral shape and have an average diameter of ca. 430 nm (Fig. 2a,c,e). Once Fe$_3$O$_4$ nanoparticles incorporated into the ZIF-8 framework, the morphology of ZIF-8 crystals is not markedly altered but the particle size decreases to ca. 250 nm (Fig. 2b,d,f and Fig. S1 for size distributions), indicating that Fe$_3$O$_4$ nanoparticles act as size-controlling agents for ZIF-8 crystals. It is also worth mentioning that there is no apparent change in the diameter of Fe$_3$O$_4$ particles in Fe$_3$O$_4$@ZIF-8 compared to the native citrate-capped Fe$_3$O$_4$ particles (9.6 ± 1.9 nm) (Fig. S2).

The encapsulation of Fe$_3$O$_4$ in ZIF-8 was further demonstrated by powder X-ray diffraction (PXRD) analysis (Fig. 2g). Fe$_3$O$_4$@ZIF-8 particles exhibit a similar XRD pattern compared to ZIF-8 indicating that the sodalite structure of ZIF-8 crystals remained unaffected after loading the Fe$_3$O$_4$ particles. Except three peaks at 2Ө = 48.75, 50.37, and 57.22°, which correspond to the (220), (311), and (400) crystal facets of magnetite (JCPDS No 19-0629), no additional peaks were detected indicating the high purity of the final Fe$_3$O$_4$@ZIF-8 particles. Thermogravimetric analysis (TGA) conducted under air indicate that Fe$_3$O$_4$@ZIF-8 particles have a slightly lower stability than ZIF-8 crystals (Fig. 3a). For ZIF-8, the sharp weight loss step of 63-64% was observed at ca. 400°C, corresponding to the decomposition of the mim' linker and to the formation of ZnO crystals. The relatively lower decomposition temperature of Fe$_3$O$_4$@ZIF-8 (350°C) compared to pure ZIF-8 might be attributed to the gradual decomposition of the citrate ligand capping Fe$_3$O$_4$ nanoparticles into aconitate and citraconate between 150 and 350°C. Finally, when comparing the weight loss of ZIF-8 and Fe$_3$O$_4$@ZIF-8 particles, the loading of Fe$_3$O$_4$ into ZIF-8 host was estimated to be 13.3%.
Textural parameters such as surface area, pore volume and pore size of \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) particles were obtained from \( \text{N}_2 \) adsorption-desorption measurements at 77K. As shown in Fig. 3b, both ZIF-8 and \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) particles display the Type I isotherms, with a steep increase for the \( \text{N}_2 \) uptake at low relative pressure, which reveals the microporosity for both types of particles. The specific surface areas, determined using the Brunauer-Emmet-Teller (BET) method, were found to be 871 ± 3 and 1856 ± 4 \( \text{m}^2/\text{g} \) for \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) and ZIF-8 particles, respectively. The pore volume was also found to decrease from 0.71 \( \text{cm}^3/\text{g} \) for ZIF-8 to 0.35 \( \text{cm}^3/\text{g} \) for \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \). The high decrease in surface area and pore volume after loading \( \text{Fe}_3\text{O}_4 \) nanoparticles into ZIF-8 are not surprising since \( \text{Fe}_3\text{O}_4 \) particles are nonporous. These results also indicate that the cavities of ZIF-8 framework are blocked by the highly dispersed \( \text{Fe}_3\text{O}_4 \) nanoparticles which seem to be mainly located at the surface of ZIF-8 crystals as indicated by TEM images (Fig. 2d,f).

The temperature dependence of the magnetization recorded in FC and ZFC conditions (\( H = 1000 \text{ Oe} \)) exhibits characteristic features of superparamagnetism for both \( \text{Fe}_3\text{O}_4 \) and \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) crystals (Fig. 4). (i) the ZFC curves go to a rounded maximum at the blocking temperature \( TB \approx 55 \text{ K} \) and \( \approx 25 \text{ K} \) for \( \text{Fe}_3\text{O}_4 \) and \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \), respectively and (ii) the room-temperature hysteresis loop points to negligible coercivity and remanence. The lower blocking temperature of \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) compared to citrate-capped \( \text{Fe}_3\text{O}_4 \) particles originates from reduced dipolar interactions between magnetic particles encapsulated in ZIF-8 pores.\(^{3,43}\) The significantly broader peak observed for \( \text{Fe}_3\text{O}_4 \) implies a distribution of blocking temperature. Since the particle size does not significantly differ for the two materials, the distribution of TB in \( \text{Fe}_3\text{O}_4 \) is likely due to variation in interparticle interactions across the sample. To compare the catalytic properties of \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) with those of pure ZIF-8 crystals, we first evaluated their catalytic activity in a Knoevenagel condensation using benzaldehyde and malononitrile as substrates and toluene as solvent (Scheme 1).\(^{43}\)

Preliminary experiments showed that the reaction proceeded efficiently at room temperature using 6 equiv. malononitrile relative to benzaldehyde and only 4 mol.% of \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) catalyst, yielding 2-(benzylidene)malononitrile in 94% yield after 3 h of reaction. Under similar experimental conditions, ZIF-8 yielded 2-(benzylidene)malononitrile in 98% yield. Fig. S3 shows the conversion of benzaldehyde when reacting with malononitrile in the presence of ZIF-8 or \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) crystals as a function of time. As seen, the condensations proceeded very quickly at room temperature with both catalysts and the reaction is only slightly slowed down using \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) crystals. These results demonstrate that the iron oxide nanoparticles incorporated in ZIF-8 framework do not alter the activity of ZIF-8 and that the reaction probably proceeds on the external surface of the catalyst.

We also conducted a control experiment in which \( \text{Fe}_3\text{O}_4 \) nanoparticles were supported on the surface of ZIF-8 crystals by soaking \( \text{Fe}_3\text{O}_4 \) particles in an aqueous dispersion of ZIF-8. When benzaldehyde was reacted with malononitrile in the presence of this catalyst, the product of the Knoevenagel condensation was obtained with a yield of 73% after 3 h reaction at room temperature. We believe that the decrease in reactivity in this case may be due to the higher occupation of ZIF-8 catalytically active surface sites. Finally, catalytic cycles were run to investigate the stability of the catalytic activity and recycling. After each run, \( \text{Fe}_3\text{O}_4@\text{ZIF-8} \) particles were separated using a magnet, washed twice with toluene and methanol, dried in air at 60°C, and reused. As shown in Fig. S4, the catalyst could be recycled at least ten times without any loss of activity for the Knoevenagel condensation between benzaldehyde and malononitrile.

The loading of magnetite nanoparticles into ZIFs was successfully extended to \( \text{Cu}^{2+} \)-doped ZIF-8 materials developed recently.\(^{44}\) Citrate-capped \( \text{Fe}_3\text{O}_4 \) were successfully immobilized in the \( \text{Cu}^{2+} \)/ZIF-8 framework and the \( \text{Fe}_3\text{O}_4@\text{Cu}^{2+} \)/ZIF-8 used for cycloaddition between benzylazide and phenylacetylene (Scheme 2).

The triazoles were obtained in 98% isolated yield using a phenylacetylene/benzylazide molar ratio of 1:2 and conducting the reaction for 3 h in toluene at 100°C. Noteworthy is the improvement of regioselectivity of the cycloaddition with \( \text{Fe}_3\text{O}_4 \)-loaded \( \text{Cu}^{2+} \)/ZIF-8 as compared to \( \text{Cu}^{2+} \)/ZIF-8 catalyst (1,4,1/5 > 99/1 for \( \text{Fe}_3\text{O}_4@\text{Cu}^{2+} \)/ZIF-8 while 1,4/1,5 = 92/8 for \( \text{Cu}^{2+} \)/ZIF-8). The \( \text{Fe}_3\text{O}_4@\text{Cu}^{2+} \)/ZIF-8 catalyst could be successfully recycled three times without any loss in activity (Fig. S5). The catalyst activity started to drop in run 4 providing triazoles in ca. 75% yield. A gradual decrease in activity was further observed and triazoles were isolated with ca. 55% yield after the 10th cycle of cycloaddition.
Blank experiments conducted in the presence of citrate-capped FeO₄ nanoparticles showed no detectable amounts of Knoevenagel or cycloaddition products and confirmed that both reactions were catalyzed by ZIF-8 materials associated to FeO₄. We also examined the leaching behaviour of FeO₄@ZIF-8 particles in Knoevenagel and Huisgen reactions. The Fe and Zn contents were determined in the crude reaction products using Inductively Coupled Plasma-Optical Emission Spectrometry (ICP-OES). Low levels for Fe leaching (207 and 39 µg/L in Huisgen and Knoevenagel products, respectively) and Zn leaching (234 and 107 µg/L in Huisgen and Knoevenagel products, respectively) were obtained. These results show that ZIF-8 crystals provide enough binding sites on the surface of FeO₄ particles to minimize deterioration and leaching and thus to facilitate efficient catalyst recycling. Finally, the XRD patterns of FeO₄@ZIF-8 and FeO₄@Cu₂O@ZIF-8 catalysts exhibit no significant changes in their crystallinity after five recyclings (Fig. S6), which further confirms their high stability.

Conclusions

To sum up, we have developed an aqueous-based route for incorporating ca 10 nm-sized FeO₄ nanoparticles inside ZIF-8 crystals and used FeO₄@ZIF-8 particles as a heterogenous catalyst for Knoevenagel condensations between benzaldehyde and malononitrile. The FeO₄@ZIF-8 catalyst is easily recoverable by magnetic separation and can be reused more than ten times without any loss in the catalytic activity. Using the same approach, FeO₄ particles were also loaded into Cu²⁺-doped ZIF-8 crystals and the particles obtained were successfully used for Cu²⁺-catalyzed Huisgen cycloadditions. Results obtained in this study open an avenue to the fabrication of highly efficient and easily recoverable MOFs based nanocatalysts.
