This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Construction of Ni\textsuperscript{II}Ln\textsuperscript{III}M\textsuperscript{III} (Ln = Gd\textsuperscript{III}, Tb\textsuperscript{III}; M = Fe\textsuperscript{III}, Cr\textsuperscript{III}) Clusters Showing Slow Magnetic Relaxations

Chao Chen,\textsuperscript{a} Yashu Liu,\textsuperscript{b} Ping Li,\textsuperscript{a} Hongbo Zhou\textsuperscript{a} and Xiaoping Shen\textsuperscript{a,2}

Four heterotrimetallic 3d-3d'-4f complexes, \{[Ni(L)Gd(H\textsubscript{2}O\textsubscript{3})][Cr(CN\textsubscript{6})]CH\textsubscript{3}OH·2H\textsubscript{2}O \textsubscript{1}, ([Ni(L)Tb(H\textsubscript{2}O\textsubscript{3})][Cr(CN\textsubscript{6})]CH\textsubscript{3}OH·2H\textsubscript{2}O \textsubscript{2}, ([Ni(L)Gd(H\textsubscript{2}O\textsubscript{3})][Fe(CN\textsubscript{6})]3H\textsubscript{2}O \textsubscript{3} \text{and} ([Ni(L)Tb(H\textsubscript{2}O\textsubscript{3})][Fe(CN\textsubscript{6})]CH\textsubscript{3}OH·2H\textsubscript{2}O \textsubscript{4} (H\textsubscript{L} = N,N-ethylenedithio-3-methoxysilylalumimine)\} were synthesized and characterized structurally and magnetically. The X-ray structural analysis revealed that these complexes are isostructural, in which Ni\textsuperscript{II}Ln\textsuperscript{III}M\textsuperscript{III} (Ln = Tb\textsuperscript{III}, Gd\textsuperscript{III}; M = Fe\textsuperscript{III}, Cr\textsuperscript{III}) is arranged in trinuclear clusters. Then, these clusters further interact with each other via weak hydrogen bonds to form the high dimensional supramolecular networks. Magnetic investigation indicates that the Ni\textsuperscript{II}Ln\textsuperscript{III} centers are diamagnetic. Dominant antiferromagnetic coupling is presented in complexes \textsubscript{1} and \textsubscript{3}. An AC magnetic susceptibility measurement indicates that complexes \textsubscript{2} and \textsubscript{4} show typical field induced slow magnetic relaxation, which might be caused by the magnetic anisotropy of center Tb\textsuperscript{III} ions.

INTRODUCTION

The single molecule magnet (SMM)\textsuperscript{7} and single chain magnet (SCM)\textsuperscript{2} are some of the hottest topics in the research field of magnetic materials due to their potential applications in magnetic devices and quantum computers, etc. In these researches, the 3d transition metal ions such as Cr, Mn, Fe, Co, Ni, Cu, etc. are often employed to construct such materials. In particular, the magnetic anisotropy brought by Mn\textsuperscript{III}, Fe\textsuperscript{III} and Co\textsuperscript{II} was proved to be important for the SMM or SCM behaviors.\textsuperscript{3,5} At the same time, the paramagnetic lanthanide metals have also attracted much attention because of their high spin values and large magnetic anisotropy.\textsuperscript{15} As a representative work, J. R. Long and coworkers reported the SMM of (((Me\textsubscript{3}Si\textsubscript{2})\textsubscript{N})(THF)Ln)(\mu-\eta^2-\eta^2-N\textsubscript{2}) (Ln = Tb, Ho, Er) with recorded high block temperature \(T_{\text{B}} = 14\) K.\textsuperscript{6} It was found that the magnetic anisotropy of Ln\textsuperscript{III} is affected by the coordination environment, which is very interesting and stimulates the research enthusiasm for the so-called single ion magnet (SIM).\textsuperscript{7} Even so, the family of polymeric lanthanide metal complexes has the dominant position in the research field because of their interesting topological structures and magnetism. One of the branches of the research is the d-f assemblies in which the 3d/4d/5d and 4f metals are combined together to design SMMs and SCMs.\textsuperscript{1c,2d,2e,2f,8} Though the d-f magnetic complexes have been synthesized and characterized since the beginning of this century, the example of d-f based SMMs and SCMs are still scarce.\textsuperscript{16} Such a fact implies that the study on the 3d-4f magnetic systems is still at its early stage and deserves to be further explored. The advantages of the d-f magnetic assemblies can be concluded as following: (1) The system provides a broad space for researchers to design special molecular structures and tune the magnetic properties. (2) The Ln\textsuperscript{III} ions could produce significant magnetic anisotropy when the coordination field is reasonably controlled, as demonstrated by SIM.\textsuperscript{7} (3) The molecular overall magnetic anisotropy can be further enhanced by the exchange coupling between 3d and 4f spin carriers. Elegant example to this category is the (Dy\textsubscript{2}Cr\textsubscript{3}) SMM with blocking temperature of 3.7 K reported by S. K. Langley et al.\textsuperscript{17} This study highlights the essential role played by d-f combined systems in designing new SMMs with improved properties.

Against this background, the magnetic assemblies based on d-f combined systems are under investigation in our laboratory, and we have recently obtained new examples of heterotrimetallic 3d-3d'-4f complexes using the compartmental Schiff base ligand of H\textsubscript{L} (H\textsubscript{L} = N,N-ethylenedithio-3-methoxysilylalumimine). Though some relevant 3d-3d'-4f complexes such as CoCuLn,\textsuperscript{10} CrCoLn,\textsuperscript{11} CrCuLn,\textsuperscript{10a,10c,10d,12} FeCuLn,\textsuperscript{10,13} FeNiLn,\textsuperscript{14} NiCuLn\textsuperscript{15} were reported previously, there are still some systems that are not investigated up to now. To the best of our knowledge, there are no reports for the CrFeLn, CrMnLn, CrNiLn, FeCoLn, MnCuLn, MnNiLn complexes. Therefore, this field indeed deserves to further explore. In this paper, we report the first examples of CrNiLn complexes with formulas of \{[Ni(L)Gd(H\textsubscript{2}O\textsubscript{3})][Cr(CN\textsubscript{6})]CH\textsubscript{3}OH·2H\textsubscript{2}O \textsubscript{1}\} and

**EXPERIMENTAL SECTION**

**Reagents and Materials**

All the chemicals and solvents in this work are reagent grade and used as received without further purification. The Ni\(^{II}\)(L)-H\(_2\)O and [Ni(L)Ln(NO\(_3\))]\(_3\) (Ln = Gd, Dy) precursors were synthesized according to the literature method.\(^{16}\)

**Syntheses of the Complexes**

[\text{Ni}(L)\text{Gd(H2O)}_4][\text{Cr(CN)}_6]\text{CH}_3\text{OH} \cdot 2\text{H}_2\text{O} \quad (1) \text{ A methanol solution (10 ml) of the prepared } [\text{Ni}(L)\text{Gd(NO)}_3]_3 \text{ (0.1 mmol) was diffused slowly into an aqueous solution (10 ml) of K\(_3\)Cr(CN)\(_6\) (0.1 mmol) through a H-shaped tube, and the block red crystals of 1 suitable for X-ray diffraction were formed in two weeks, which were collected and washed with methanol and dried in air. **Physical measurements**

The elemental analyses for C, H and N were performed at a Perkin-Elmer 240C analyzer. The IR spectra were recorded with a Nicolet FT-170SX spectrometer. The magnetic susceptibility of the micro-crystalline samples was measured under 100 Oe from 300 to 1.8 K on a Quantum Design MPMS-XL7 SQUID magnetometer. The field dependent magnetization was recorded at 1.8-5.5 K using the applied dc field in the range from 0 to 70 kOe. The alternating current (ac) susceptibility measurements were conducted at frequencies ranging from 1 to 1500 Hz with a dc field of 0-3000 Oe and an ac field amplitude of 3 Oe. Measured susceptibilities were corrected considering both the sample holder as background and diamagnetism estimated from Pascal constants.\(^{17}\)

**X-ray crystallography**

Single crystal X-ray crystallographic diffraction data were collected at 173 K on a Bruker SMART APEX CCD area detector diffractometer. Graphite-monochromated Mo K\(_\alpha\) radiation (\(\lambda = 0.71073 \text{ Å}\)) and the \(\phi\) and \(\omega\) scan mode were adopted for the data collection. Diffraction data analysis and reduction were performed with the programs of SMART, SAINT and XPREP.\(^{19}\) The structures were solved based on direct methods and refined by a full-matrix least-squares method on \(F^2\) using the SHELXL crystallographic software package.\(^{19}\) All the non-hydrogen atoms were located in difference Fourier maps and refined anisotropically. thermal parameters, while all of the hydrogen atoms were added geometrically at idealized positions, and included in the refinement of isotropical thermal parameters with the \(U\) values fixed using a riding model. The water-H atoms were not able to be located from the residual peaks and they were not found in the structures. Besides, the methanol molecules in 1 and 2 are not present with unit occupancy, and they were allowed an anisotropic free variable refinement with partial occupancies. Crystallographic data for 1–4 are summarized in Table 1.
Table 1. Details of the crystal data and structural refinement parameters of 1–4.

The crystal structures of complexes 1-4 are shown in Figure 1 and Figure S1 (see Supporting Information). The intermolecular short contacts and packing structures for the four complexes are shown in Figure S2.

RESULTS AND DISCUSSION

Syntheses and Characterization

According to previous reports, the reaction of NiII(L)·H₂O, Ln(NO₃)₃ and additional hexacyanometallates can form different structures. In most cases, the one-pot reaction of these precursors would produce polynuclear clusters in which the nickel atoms are involved in the coordination to hexacyanometallates, leading to the formation of interesting hexanuclear or octanuclear molecular cycles. In our present work, the reaction route was divided into two steps, as illustrated in Scheme 1, and the trinuclear clusters of 1-4 were formed. The relatively low nuclearity clusters of 1-4 might be limited by the square planar coordination geometry of low spin Ni(II) centers presented in [Ni(II)Ln(NO₃)₃] moieties. The IR spectrums verify the structures of complexes 1 – 4. The characteristic absorption peaks at 2100-2150 cm⁻¹ can be assigned to the cyanoide group, and the other absorption bands are ascribed to the characteristic absorptions of the Schiff base ligands.

Crystal Structures

The selected structural parameters such as key bond distances and angles are listed in Table S1. The crystal structures of complexes 1-4 are shown in Figure 1 and Figure S2 (see Supporting Information). The intermolecular short contacts and packing structures for the four complexes are shown in Figure S2.
type ligand occupies four vertex positions. The Ni-N/O bond distances (1.830(4) - 1.851(3) Å) are very close to each other, which is comparable to the bond parameters shown in mononuclear Ni\(\text{III}\) (salen-type) complex.\(^{21}\) The center Tb ion is nine-coordinated and adopts nonsymmetrical TbO\(_8\)N coordination sphere. Such a coordination fashion is typical for the lanthanide 4f metal ion.\(^{16}\) The Tb-O\(_{\text{phenano/h2o}}\) bond distances (2.335(3) - 2.516(3) Å) are somewhat shorter than those of Tb-O\(_{\text{methoxy}}\) (2.608(3) - 2.663(3) Å). The bond angles of Ni1-O1-Tb1 and Ni1-O2-Tb1 are 105.81(1)° and 106.13(1)°, respectively.

The dihedral angle between the planes defined by Ni1O1O2 and Tb1O1O2 is 14.8°, which is somewhat larger than those for the 3d-4f Ni\(\text{II}\)Ln\(\text{III}\) dinuclear complexes.\(^{16}\) For the hexacyanometalates moiety, the [Cr(CN)\(_6\)]\(^{3-}\) coordinates to Tb\(^{III}\) ion through one of its six cyano groups, leaving the rest cyano groups terminal. The Cr-C bond distances are in the range of 2.057(5) - 2.079(5) Å, which are typical of Cr-C bond lengths. The Tb-N\(_{\text{cyano}}\) bond distance is 2.475(4) Å, which is larger than the usual scope for 3d-N distance and coincides with typical 4f-N separations. The Cr-C-N angle is almost linear (172.6(4) - 178.8(4)°) while the Tb-N\(_{\text{cyano}}\) angle (162.9(3)°) deviates from linearity. Moreover, the molecular plane for salen-type ligand is somewhat distorted (dihedral angles between two aromatic rings planes (C7-C12; C7-C22)) are 22.1°, which could be ascribed to the TbO\(_8\)N coordination sphere presented in the cavity of salen-type ligand. For the extended structure, the weak hydrogen bond contacts between the terminal cyano nitrogen atoms and the coordinated water molecules lead to the formation of 2-D networks along \(ab\) plane, which further stack layer by layer along \(c\) axis. (Figure S1-2)

**Magnetic Properties**

DC magnetic susceptibility measurements for complexes 1 - 4 were carried out on the polycrystalline sample at 100 Oe in the temperature range of 1.8–300 K (Figure 2a). At room temperature, the \(\chi_m T\) values for 1 - 4 are 9.7, 12.9, 9.0 and 12.1 cm\(^3\) K mol\(^{-1}\), respectively, which are close to the expected values for uncoupled Ln\(\text{III}\)-Cr\(\text{III}/\text{Fe}^{\text{III}}\) units (Theoretical value: \(9.76\) cm\(^3\) K mol\(^{-1}\) for 1; \(13.7\) cm\(^3\) K mol\(^{-1}\) for 2; \(8.25\) cm\(^3\) K mol\(^{-1}\) for 3 and \(12.19\) cm\(^3\) K mol\(^{-1}\) for 4, respectively \(\Sigma S = 7/2, S_C = 3/2, S_{\text{Oe}} = 1/2, g = 2, Tb^{3+}; J = 6, g_J = 1.5\)). The room temperature \(\chi_m T\) values of 1 - 4 suggest that the Ni\(\text{III}\) ion is diamagnetic.\(^\text{16}\) Upon cooling, the \(\chi_m T\) values for 1 and 3 keep almost constant in the high temperature region, while a continuous decrease is observed for 2 and 4. In the very low temperature zone, the \(\chi_m T\) values for 1- 4 all show rapid decrease and reach the minimum values of 2.8, 5.7, 8.0 and 9.0 cm\(^3\) K mol\(^{-1}\), respectively, at 1.8 K. Considering that the Ni\(\text{III}\) center is diamagnetic, complexes 1 and 3 were treated as Gd\(\text{III}^{\text{III}}\)-M\(\text{III}\) (\(M = \text{Cr, Fe}\)) dinuclear units and the Kambe's method\(^\text{25}\) was used to fit the susceptibility data. The appropriate Hamiltonian is \(H = -2J_{\text{Sd}} S_{\text{Oe}} U\) (\(U\) represents the intramolecular Gd-M coupling constant). Based on this model, the data of 1 and 3 in the whole temperature region was simulated, affording the best match parameters: \(J = -0.4\) cm\(^{-1}\), \(g = 2.0, R = 2.3 \times 10^{-4}\) for 1 and \(J = 0.12\) cm\(^{-1}\), \(g = 2.1, R = 1.1 \times 10^{-4}\) for 3, respectively. The result indicates the coupling nature between Gd\(\text{III}\) and M\(\text{III}\) is both antiferromagnetic, which is comparable to other related Gd\(\text{III}^{\text{III}}\)-M\(\text{III}\) (\(M = \text{Cr, Fe}\)) bimetallic systems.\(^\text{23}\) To verify the result, the field dependence magnetization was measured under different temperatures (Figure 2b). The experimental \(M\) vs \(H\) curves of complexes 1 and 3 could be well simulated (Using Magpack program)\(^\text{24}\) based on the set of parameters extracted from the susceptibility data, further confirming the parameters obtained are reasonable. The linear increase feature of the \(M-H\) curve for 1 at 1.8 K implies the presence of

![Figure 2](image-url)
antiferromagnetic Gd\textsuperscript{III} - Cr\textsuperscript{III} state. As the dc field further increases, the magnetization value continuously increases and reaches the value of 9.7 N\textsubscript{H} at 70 kOe. The value is close to that expected for the ferromagnetic state (10 N\textsubscript{H} calculated from M\textsubscript{S} = g(S\textsubscript{Gd} + S\textsubscript{Cr}), with g = 2), indicating antiferromagnetic Gd\textsuperscript{III} - Cr\textsuperscript{III} state can be overcome by strong applied dc field. For complex 3, the M-H curves are smoother than that of 1, indicating the Gd\textsuperscript{III} - Fe\textsuperscript{III} antiferromagnetic coupling is very weak and the system does only show paramagnetic properties. The magnetic behaviors of 1 and 3 are typical of the dinuclear metallic clusters containing isotropic spin carriers.

For 2 and 4, the analysis of dc magnetic behaviors is difficult. The previous studies have revealed that the Tb\textsuperscript{III} - M\textsuperscript{II} (M = Cr, Fe) prefer to antiferromagnetic interaction.\textsuperscript{25} Therefore, the continuous decrease of the \(\chi_M T\) vs \(T\) curves of 2 and 4 upon cooling might be caused by both the intramolecular antiferromagnetic coupling and the thermal depopulation of the Stark sublevels of the 4f ion. The \(M\) vs \(H\) curves of 2 and 4 (Figure S2b) both reveal that the magnetizations at 70 kOe are far from saturation (12 N\textsubscript{H} and 10 N\textsubscript{H} for 2 and 4, respectively, calculated from M\textsubscript{S} = g(S(M) + g(J(T)) \), which might be induced by the magnetic anisotropy and/or the population of low-lying excited states of Tb\textsuperscript{III} ions.\textsuperscript{26} Considering that complexes 2 and 4 which contain the Tb\textsuperscript{III} ions might exhibit SMM behaviors, the ac measurement was performed. The field-dependent ac susceptibilities under different dc field (0 Oe to 3 kOe) at 1.8 K were firstly measured to verify the existence of slow magnetic relaxations (Figure S3). The result indicates that both the complexes show field induced slow magnetic relaxations when a suitable dc field is applied. The optimum dc field was determined from the field-dependent susceptibilities to be 1 kOe for 2 and 2 kOe for 4, respectively. Such behaviors obviously indicate the presence of quantum tunneling effect in the systems that can be suppressed by the dc field. To study the relaxation dynamics, the frequency- and temperature dependent (Figure 3 and Figure S4) ac susceptibilities under fixed dc field (1 kOe for 2 and 2 kOe for 4) respectively were then measured. The result reveals that both the in-phase (\(\chi_M''\)) and out-of-phase (\(\chi_M''\)) susceptibilities of 2 and 4 are frequency- and temperature dependent. For 2, the peaks in the frequency dependent out-of-phase (\(\chi_M''\)) curves are clearly observed. The relaxation time and effective energy barrier were extracted by fitting (Figure S5) to Debye model\textsuperscript{27} and the Arrhenius equation \(\tau = \tau_0 \exp(U/k_B T)\) (where \(\tau_0\) is a preexponential factor, and \(U\) is the energy barrier), affording the parameters \(\tau_0 = 1.1 \times 10^5\), \(U = 3.0\, \text{cm}^{-1}\). The relatively small \(U\) and large \(\tau_0\) values indicate the relaxation process is significantly affected by the quantum tunneling even at the case that the dc field is applied. The Cole-Cole curves of 2 in the temperature range of 1.8-14 K are plotted in Figure 4. The shape of the plotted Cole-Cole curves deviates from one single semicircle, indicating the presence of different relaxation processes with different relaxation times.

Indeed, the fitting of the semicircles to Debye model based on single relaxation process does not give satisfactory result. So, a modified Debye model\textsuperscript{28} for double relaxation process is used to fit the data of complexes 2, giving the parameters which are listed in Table S2. For complex 4, no peaks are detected for the frequency dependent out-of-phase (\(\chi_M''\)) curves but the peaks appear in the temperature dependent out-of-phase (\(\chi_M''\))
curves. The Cole-Cole curves of complex 4 are shown in Figure S6, it can be seen that the same curves show typical V-shape, which could be assigned to be the overlap of two different relaxation processes. The phenomenon that deviates from a single magnetic relaxation behavior for 2 and 4 is also observed for other Dy or Tb based SMMs, and could be explained by the coexistence of thermal excitation and quantum tunneling mechanism, further confirming the important role of quantum tunneling played in the magnetic relaxation at very low temperature.

Conclusions

In summary, four new examples of the complexes derived from 3d, 3d′ and 4f ions have been synthesized with the assistance of a compartmental Schiff base ligand. The structural analysis reveals that these complexes show a \( \text{Ni}^{2+}\text{Ln}^{3+}\text{M}^{3+} \) (M = Cr, Fe) trinuclear cluster structure. The magnetic studies reveal that complexes 1 and 3 show weak intramolecular antiferromagnetic interactions, while complexes 2 and 4 show interesting field induced slow magnetic relaxation behavior in low temperatures due to the contribution brought by anisotropic Tb\(^{3+}\) ions. Considering that the relaxation behaviors of these systems are a function of both the coordination environment around the anisotropy 4f spin carriers and the magnetic coupling exchanges, their magnetic properties could be possibly improved by a rationally modification of the molecular topological structures. The related work is under way in our group.
