Practical and High Sensitive C₃N₄-TYR Fluorescent Probe for Convenient Detection of Dopamine

Hao Li¹, Manman Yang‡, Juan Liu, Yalin Zhang, Yanmei Yang, Hui Huang*, Yang Liu*, Zhenhui Kang*

The C₃N₄-tyrosinase (TYR) hybrid, as a fluorescent probe, is highly accurate, sensitive and simple for the detection of Dopamine (DOPA). Under the optimized conditions, the relative fluorescence intensity of C₃N₄-TYR is proportional to the DOPA concentration in the concentration range from the 1×10⁻⁷ to 3×10⁻⁸ mol L⁻¹ with correlation coefficient of 0.995. In the present system, the detection limit is achieved to 3×10⁻⁸ mol L⁻¹. Notably, those quantitative detection results of clinical samples are comparable to those of the high performance liquid chromatography methods. Moreover, the enzyme-encapsulated C₃N₄ sensing arrays on glass slide and test paper were performed, which reveals the sensitive sensing and excellent stability. The results reported here provide a new approach to design multifunctional nanosensor for the detection of bio-molecules.

Introduction

Dopamine (DOPA) is an important neurotransmitter and hormone for people and animals in the catecholamine and phenethylamine families,¹ which is implicated in locomotion, reward and motivation.² If the deficiency of DOPA in the brain beyond the normal that will cause in pathogenesis of neurological disorders such as Parkinson's disease, Schizophrenia and Huntington's disease.³⁻⁴ Therefore, this has sparked significant interest for the development of detection methods for DOPA. Various analytical methods such as high performance liquid chromatography (HPLC) and electrochemical techniques have been used for the detection of DOPA.⁵ However, these methods need complicated pre-concentration, time-consuming steps, high-cost instruments, and sophisticated equipment, which tremendously limit their wide application. Therefore, an easy, exact and fast method for the detection of DOPA is highly needed.

Compared with conventional analytical techniques, fluorescent biosensor,⁶ as a new class of detection method, has caused a great deal of attention for the detection of DOPA due to its high sensitivity, low cost and practicality. As known, the practical fluorescent biological probes should satisfy three points as follows: firstly, the emission spectroscopy of biosensor must match the absorption spectrum of dopaminechrome (products of oxidation by the enzyme). Secondly, the fluorescent sensor material should have the proton (H⁺) adsorption and/or electron acceptors ability. Thirdly, the fluorescent sensor material should possess low toxicity and biocompatibility. Recently, the semiconductor-based quantum dots (QDs) are regarded as powerful inorganic fluorescent probes.⁹ For example, Yuan et al. used the CdTe quantum dots as a fluorescent indicator to detect the DOPA (detection limit: 0.05 μM, detection range: 50-1000 μM). However, the potential toxicity, and poor biocompatibility limit its further practical applications.¹¹

C₃N₄ has attracted more attention due to the easy preparation, high quantum yield, non-toxicity, low cost, good biocompatibility and excellent photostability.¹²⁻¹⁷ Particularly, the N-contain-structure make it possess strong proton adsorption ability, which is helpful for the fluorescent biosensor design towards the high sensitive detection of DOPA. Herein, we report the C₃N₄-tyrosinase (TYR) as a fluorescent probe (C₃N₄-TYR), which exhibits high accuracy, sensitivity, and simple for the detection of DOPA. In the detection system, the DOPA can be oxidized by TYR to form dopaminequinone, which subsequently quickly be oxidized to dopaminechrome in phosphate buffer (PB). The absorption spectrum of dopaminechrome has heavy overlap with the fluorescence spectrum of C₃N₄, which significantly quenched the fluorescence of C₃N₄. Based on the C₃N₄-TYR fluorescent probe, good linear correlations were obtained in the concentration range from 1×10⁻³ to 3×10⁻⁸ mol L⁻¹ with the detection limit of 3×10⁻⁸ mol L⁻¹ for the detection of DOPA. Notably, the quantitative detection results of clinical samples are comparable to those of the high performance liquid chromatography (HPLC) method. Moreover, the C₃N₄-TYR sensing arrays on glass slide and test paper were successfully...
performed, which reveals the sensitive sensing and excellent stability.

Experimental

Chemicals

Urea and melamine were purchased from Sigma-Aldrich. Tyrosinase (TYR, 845 U/mg) and dopamine were purchased from USA Worthington Biochemical Co. Ltd. All other chemicals used in this work were of analytical grade. Except the specific statement, the detection buffer was PB buffer (pH = 6.8, 0.05 mol L⁻¹ sodium phosphate). Milli-Qultrapure water (Millipore, ≥ 18 MΩ cm) was used throughout.

Characterization

Transmission electron micrographs (TEM) were taken on a FEI/Philips Tecnai G2 F20 (200 kV) TWIN TEM. Scanning electron microscopy (SEM) images were obtained using FEI-quanta 200 scanning electron microscope with acceleration voltage of 20 kV and coupled with an energy-dispersive X-ray analysis (EDX) spectrometer. The Fourier transform infrared (FTIR) spectra were obtained with a Bruker Fourier Transform Infrared Spectrometer (Hyperion). Photoluminescence (PL) study was carried out on a Horiba Jobin Yvon (FluoroMax 4) Luminescence Spectrometer, while UV–Vis spectra were obtained with an Perkin Elmer Lambda 750 spectrophotometer. Powder X-ray diffraction (PXRD) data were collected on a X’Pert-ProMPD (Holand) D/Max-γ AX-ray diffractometer with Cu Kα radiation in a flat plate geometry. Atomic force microscopy (AFM) measurements were performed on Veeco Multimode V Atomic Force Microscope. The scans were performed in the tapping mode, using a silicon tip. The Brunauer–Emmett–Teller (BET) specific surface areas and pore size distributions were calculated by plotting the adsorption isotherm of N₂ at liquid N₂ temperature (77 K). These measurements were made on Micromeritics ASAP 2050 porosimeter. DOPA detection using high-performance liquid Chromatography (HPLC) was conducted on HP Agilent 1100 Series HPLC.

Synthesis of C₃N₄

The C₃N₄ powder was obtained by directly heating the urea in a semi-closed system with one-step heat treatment. 5 g urea was added in a crucible. Then the crucible was directly heated to 550 °C at a rate of 5 °C min⁻¹ and then kept at this temperature for another 3 h in a muffle furnace.¹⁸

Synthesis of nonporous-C₃N₄ (g-C₃N₄)

The g-C₃N₄ was prepared according to the literature.¹⁹ The nonporous-C₃N₄ powder was obtained by directly heating the melamine in a semi-closed system with two-step heat treatment. Typically, 10 g of melamine was put into an crucible with a cover and first heated at a rate of 20 °C min⁻¹ to 500 °C in a muffle furnace and kept at this temperature for 2 h. Then deammonation treatment was conducted at 550 °C for 2 h (at a a rate of 20 °C min⁻¹).

Preparation of C₃N₄-TYR

In a 50 mL glass tube, the obtained C₃N₄ (0.0168 g), 20 ml phosphate buffer (PB, 0.05 mol L⁻¹, pH = 6.8) and enzyme tyrosinase (TYR, 0.04 g) were added. The mixture was stirred at 4 °C for 24 h in cold water bath. Then the mixture was centrifuged (10000 rpm, 30 min) and washed with PB solution for several times. At the same time, the wet C₃N₄-TYR powder was lyophilized by the freeze dryer. Finally, 0.05 g freeze-drying C₃N₄-TYR powder was added in 5 mL PB solution, the C₃N₄-TYR solution (0.01 g/mL) was prepared.

Analysts Sensing by PL Detection

For all tests and reactions, the experiments were repeated at least three times to ensure the accuracy of the measurement. All of the PL spectra were recorded on a fluorescence spectrophotometer. The emission spectra were recorded under the excitation wavelength of 390 nm. For the study of the quenching effect of dopamine on TYR-encapsulating C₃N₄ powder, 0.2 mL TYR-encapsulating C₃N₄ was mixed with phosphate buffer (3 mL). Then the dopamine solutions with different concentrations were added into the mixture. Finally, the mixture was incubated at 35 °C for 40 min for fluorescence measurements.

C₃N₄-TYR Sensing Arrays on Glass Slide

The prepared C₃N₄-TYR (2 μL, 0.01 g/mL) was dropped on glass slides, dried by evaporation, and stored at 5 °C. For the analytical sensing, dopamine solution (2.5 μL) of various concentrations were dropped on the sensing arrays and left to interact for 1 min. Fluorescence of the sensing array was observed under excitation with 365 nm light of a UV lamp.

C₃N₄-TYR test paper

The filter papers were immersed into the solution of C₃N₄-TYR (0.003 g/mL). Then dopamine of different concentration was dropped on the filter paper and stored for 40 min at 4 °C. Fluorescence of the test paper was observed under excitation with 365 nm light of a UV lamp.

Adsorption Equilibrium Measurements

In order to study the proton (H⁺) adsorption capacity of C₃N₄, the same concentration 0.005 M HCl solution was selected to investigate the adsorption behaviour of C₃N₄. Because of the water solubility of C₃N₄, the adsorption experiments were conducted with a dialysis method. The C₃N₄ solution was dialyzed using a semi-permeable membrane (MWCO 1000) in a 1000 mL beaker, and the dialysate was 0.005 M HCl (600 mL). Notably, the C₃N₄ was treated previously by dialysis method before using, so, C₃N₄ would not dialyze out of semi-permeable membrane. If C₃N₄ has good adsorption behaviour of H⁺, H⁺ would gradually cross semi-permeable membrane and dialyze into C₃N₄ solution. After stirring on a shaker for predetermined time intervals, the residual concentration of HCl solution was determined by titrating with 0.005 M NaOH solution.

Data Normalization Method

In order to make the data referenceable, all of the PL spectra were normalized. The peak intensity of PL spectra at 440 nm
was selected as a standard. For detecting the dopamine, the normalized intensity was the ratio of I and I₀, where I and I₀ are the PL intensities of the C₃N₄ in the presence and absence of dopamine, respectively. For investigating the effect irradiation time, temperature, ionic strength and pH to the stability of C₃N₄, and studying the influence of temperature, pH values and incubation time on the reaction system, the normalized intensity was obtained by using the maximum intensity of measurement as reference.

The Detailed Analysis of Michaelis-Menten Equation

In order to test the enzyme activity, Michaelis-Menten analysis was performed. The classic Michaelis-Menten mechanism provides a highly satisfactory description of catalytic activities for large ensembles of enzyme molecules. It yields the relationship between the initial velocity (V) and the substrate concentration [S].

\[ V = \frac{[S] V_{\text{max}}}{[S] + K_m} \]

Where, \( V_{\text{max}} \) is the maximum velocity of the enzymatic reaction and \( K_m \) is the Michaelis constant representing the concentration of substrate at half of the maximum velocity.

\[ \frac{1}{V} = \frac{K_m}{V_{\text{max}}} \left( \frac{1}{[S]} + \frac{1}{V_{\text{max}}} \right) \]

By plotting 1/V with 1/[S], the ordinate intercept of the obtained graph is equivalent to the inverse of \( V_{\text{max}} \), the abscissa intercept of the graph represents \(-1/K_m\). Thus, both \( K_m \) and \( V_{\text{max}} \) values can be calculated.

Results and Discussion

As shown in Figure 1A, the typical TEM image indicates that the obtained C₃N₄ has a thick-layered structure. While Scanning Electron Microscope (SEM) image (Figure 1A) further shows the loose and soft agglomerates with a size of several micrometers. The inset in Figure 1A (the energy-dispersive X-ray (EDX) spectrum) indicates the ratio content of C elements and N elements is about 3:4, further confirming the formation of C₃N₄. The XRD pattern of C₃N₄ is shown in the inset of Figure 1A. The strong peak at 27.57° is the characteristic interlayer stacking peak of aromatic systems, which is indexed for graphitic material as the characteristic interlayer stacking peak of aromatic systems. A further peak at 13.14° is due to the interlayer stacking, which is indexed as (100) and corresponding to an interlayer distance of \( d = 0.675 \) nm. UV/Vis absorption spectrum (Figure S2, black line) indicates the absorbance edge of the obtained C₃N₄ around 460 nm, corresponding to the intrinsic band gap of C₃N₄ (2.7 eV). Figure S2 (red line) shows the FTIR spectrum of C₃N₄. The peak at around 3500 cm⁻¹ corresponds to the N-H stretching. Several bonds in the 1200-1650 cm⁻¹ region are associated with the typical stretching modes of C-N heterocycles. The bond at 810 cm⁻¹ is corresponding to the characteristic breathing mode of the triazine units. Further, Brunauer-Emmett-Teller (BET) surface area, adsorption and the pore size distribution were analyzed. Nitrogen adsorption and desorption isotherms of C₃N₄ is shown in Figure 1B. The result displays that the isotherm is a Type IV isotherm with a hysteresis loop, which is characteristic curve of mesoporous structures. The inset in Figure 1B displays the pore size distribution of C₃N₄ from the desorption branch using the BJH model, which mainly distribute at about 34 nm, and have a broad peak at 10-70 nm. The BET specific surface area of C₃N₄ is measured to be 103.4 m² g⁻¹. The morphology of C₃N₄ and C₃N₄-TYR is further observed on AFM, and the images are shown in Figure 1C and 1D respectively. In Figure 1D, the Elliptically-shaped features with sizes of about 10 nm, which is consistent well with the shape and size of TYR. The SEM image of C₃N₄-TYR (shown in Figure S1B) also shows the round-shaped or elliptically-shaped of C₃N₄-TYR, further implying that enzyme (TYR) has been successfully encapsulated to the C₃N₄.

To study their stability, C₃N₄-TYR was washed with phosphate buffer thoroughly. After washing, the supernatant displays no obvious enzyme catalytic activity on the DOPA (TYR-catalyzed oxidation of DOPA, see Figure 2A), whereas the enzyme catalytic activity in C₃N₄-TYR is well maintained. Figure 2B shows absorption spectra of DOPA after washing an storage for 25, 31, 73, 83, 130, 142 and 202 h. It can be seen that it has no distinct change even after storage for 202 h which suggests that C₃N₄ offers a good way to encapsulate TYR so as to keep the enzyme activity for a long time. To further confirm the increased enzyme activity in the C₃N₄ is due to the large surface area and the porosity of C₃N₄, a control experiment is carried out, g-C₃N₄ with small surface area of 7 m² g⁻¹ (prepared by directly heating the melamine, see Figure 2C) is used to fabricate the C₃N₄-TYR hybrid instead of the porous C₃N₄. It is found that nonporous-C₃N₄-TYR hybrid also...
washing shows no obvious enzyme activity on the DOPA (shown in Figure 2D). Therefore, it can be concluded that C3N4 with the large surface area and the porosity could provide an excellent matrix so that the enzyme activity can be well maintained.

Figure 2 (A) Absorption spectra of dopamine after incubation with supernatant before and after washing the C3N4-TYR, C3N4-TYR just after washing (35 °C, pH = 6.8). (B) Absorption spectra of dopamine after incubation with C3N4-TYR after washing and storage for 25, 31, 73, 83, 130, 142 and 202 h (35 °C, pH = 6.8). (C) Nitrogen adsorption-desorption isotherms g C3N4 from 0 to 1 bar at 77 K, inset is the TEM image of nonporous C3N4. (D) Absorption spectra of dopamine after incubation with supernatant before and after washing the nonporous-C3N4-TYR (g-C3N4-TYR), porous-C3N4-TYR (g-C3N4-TYR) just after washing (35 °C, pH = 6.8).

To further test the enzyme (TYR) catalytic activity of C3N4-TYR system, Michaelis-Menten analysis was performed. As shown in Figure 3A, the Michaelis–Menten behaviour could clearly be observed. Michaelis constant of C3N4-TYR (0.448 mmol L\(^{-1}\)) is about 1.4 times of that of the free enzyme (0.32 mmol L\(^{-1}\)). The maximum velocity of TYR in the C3N4 (0.25 mmol L\(^{-1}\) per min) is 92.5% of that of free TYR. It can be concluded that C3N4 provides a good matrix to encapsulate TYR without obvious structural changes and allows for relatively fast diffusion of substrate to the enzyme, which may be contributed to the large surface area and the porosity of C3N4.

As discussed above, the highly efficient fluorescent biosensor for DOPA detection should have stable emission, a suitable PL spectrum (match the absorption spectrum of dopaminechrome) and good proton adsorption ability. In the following study, we investigated the influence of irradiation time, temperature, ionic strength and pH on the fluorescence intensity of C3N4. As illustrated in Figure S3A, PL intensity of C3N4 is very stable with no obvious photobleaching loss after irradiation with the Hg-lamp (365 nm) for even 10 h. Figure S3B displays the effect of temperature on the normalized fluorescence intensity of C3N4 in the PB solution. It can be seen that when the temperature increases from 10 to 50 °C, the PL intensity of C3N4 is almost the same, which indicates that the temperature does not affect the PL intensity of C3N4. In order to study the effect of ionic strength on the fluorescence intensity of C3N4, the NaCl solution with ionic strength from 0.2 to 2.0 mol L\(^{-1}\) was added into solution at room temperature (Figure S3C). The results showed that the fluorescence intensity of C3N4 did not change even in aqueous solution with a high ionic strength (2 mol L\(^{-1}\) NaCl). The effect of pH on the fluorescence intensity of C3N4 was also studied. As can be seen from Figure S3D, no apparent change of fluorescence intensity of C3N4 is observed in the pH range of 2–12, indicating pH has a little effect on the fluorescence intensity of C3N4. From above discussion, it can be concluded that C3N4 can keep stable under Hg-lamp irradiation, high temperature, high ionic strength and strong acid or strong alkaline environment, which makes it a potential fluorescent probe candidate for the detection of bio-molecules. In the following studies, the proton adsorption experiment of C3N4 was also investigated. The adsorption experiments were conducted with a dialysis method (see experimental section for details). The amount of adsorbed HCl, Q (mg/g) were calculated by the following equation:

\[
Q = \frac{(C_0 - C_e)V}{1000W}
\]

Where \(C_0\) and \(C_e\) are the initial and equilibrium concentration (mg/L), respectively, \(V\) is the volume of HCl solution (mL) and \(W\) is the weight (g) of C3N4 adsorbent. The adsorption behaviour of C3N4 was conducted at the same condition, and the concentration and volume of C3N4 solution were same. Figure 3B shows the dependence of contact time on removal of H\(^+\) by C3N4 from which the adsorption of H\(^+\) was extraordinary rapid in the first 24 min, then gradually increased as the prolongation of contact time. After 30 min of adsorption, the amount of H\(^+\) remains constant, which suggests that 6 min is the equilibrium time in this adsorption experiments. And the amount of adsorbed H\(^+\) (based on the quality of HCl) is about 13.12 g/g. These results indicate that C3N4 possesses absorption capacity of H\(^+\), which makes C3N4 more sensitive for the DOPA detection.

![Figure 3](image)

Figure 3 (A) Line weaver-Burk analysis of the enzymatic kinetics of free TYR and TYR in the C3N4. The concentrations of DOPA were 1.0, 1.5, 2.0, 2.5, 4.0, and 5 mmol L\(^{-1}\). Phosphate buffer (0.05 mol L\(^{-1}\), pH = 6.8); incubation time 2 min. (B) Dependence of contact time on removal of H\(^+\) by the C3N4.

As shown in Figure 4A and 4B, they displays UV/Vis absorption spectrum of dopaminequinone (DOPA) was converted to dopaminechrome by a rapid spontaneous auto-oxidation in present of TYR, see Figure 5) and the PL spectrum of C3N4 from 325 to 750 nm when excited at 390 nm. It can be seen that dopaminechrome gives rise to strong absorption at \(\lambda_{\text{max}} = 470\) nm, and C3N4 has a strong emission at about 450 nm. The absorption spectrum of dopaminechrome has heavy overlap with the fluorescence spectrum of C3N4. Therefore, the...
PL of C₄N₄ should be significantly quenched by the dopaminechrome originated from the catalyzed product of the DOPA. To investigate the quenched fluorescence signal, the fluorescence spectra of C₄N₄, C₄N₄-TYR, C₄N₄-DOPA and C₄N₄-TYR-DOPA were recorded. As can be seen from Figure 4C, the spectra of C₄N₄, C₄N₄-TYR, C₄N₄-DOPA is almost the same. However, the fluorescence intensity of C₄N₄-TYR-DOPA is quenched significantly. Therefore, it can be concluded that the quenched fluorescence intensity of C₄N₄ is resulted from the dopaminechrome. All above results (porous structures, good photostability, strong proton H⁺ adsorption ability, and the heavy overlap between the emission spectrum of C₄N₄ and the absorption spectrum of dopaminechrome) suggests that the C₄N₄-TYR could be used as a fluorescent probe for the high sensitive detection of DOPA. In the following studies, the factors like temperature, pH values and incubation time were optimized. As shown in Figure 4D, the I₀/I reaches maximum when the temperature is 35 °C. Figure 4E displays the effects of pH on the fluorescence intensity of the reaction system. The results reveal that the fluorescence intensity of DOPA detection system (pH = 6.8) is most noticeably quenched in the same dopaminechrome system. The curve in Figure 4F indicates that maximal quenched signal is achieved with 40 min of incubation and then sustains a stable value. Hence, to ensure complete fluorescence recovery and obtain stable signal, fluorescence intensity was recorded after the system had reacted for 40 min. Therefore, all further experiments were performed at 35 °C, pH = 6.8 and an incubation time of 40 min.

![Figure 4](image-url)

**Figure 4** (A) UV/Vis absorption spectrum of dopaminechrome, inset: photograph of dopaminechrome under UV (365 nm, center) light. (B) UV/Vis absorption spectrum of dopaminechrome (orange trace) and the PL spectrum of C₄N₄ (green trace). (C) Fluorescence spectra of C₄N₄, C₄N₄-TYR, C₄N₄-DOPA, C₄N₄-TYR-DOPA (35 °C, pH = 6.8, the concentrations of dopamine and TYR: 3.12×10⁻⁵ mol·L⁻¹ and 0.1 mg mL⁻¹). Effects of temperature (D), pH values (E) and incubation time (F) on the fluorescence intensity of C₄N₄-TYR-DOPA detection system.

Under the optimal conditions, the sensing of C₄N₄-TYR to DOPA was conducted. As shown in Figure 5A and 5B, the fluorescence intensity of C₄N₄-TYR is markedly quenched in the presence of DOPA. The ratio I₀/I (I₀ and I₀ are fluorescence intensity of C₄N₄-TYR in the presence and absence of DOPA, respectively) is proportional to the DOPA concentration with the linear regression equation being I₀/I=1.10×2979.19CDOCOPA (R² = 0.995). The detection limit of DOPA is 3×10⁻⁶ mol·L⁻¹, the detection range is from 3×10⁻⁶ to 1×10⁻³ mol·L⁻¹. The detection limit is lower than ever reported methods and the detection range is comparable to some recently reported methods, which indicates that C₄N₄-TYR has a promising application for the detection of DOPA.

To evaluate the selectivity of the proposed method, we studied the fluorescence response of C₄N₄-TYR to DOPA in the presence of different potential interfering substances. The potential interfering substances include common dopaminechrome analogues, amino acids and common ions. The results are shown in Figure 5C. Several dopaminechrome analogues have little effect on DOPA detection even at concentrations 30 times higher than that of DOPA, indicating the high specificity of the proposed biosensors. Amino acids and common ions also shows little influence on the detection of DOPA. These results suggest that C₄N₄-TYR can be used as reliable sensor for the high selective detection of DOPA.

In order to investigate the accuracy of the developed detection system for DOPA, the detection of DOPA by the HPLC was performed. The DOPA concentration in urine samples of healthy subjects is between 100 and 400 mg/24 h. Notably, this detection method based on C₄N₄-TYR could be directly used in real samples based on its high sensitivity and selectivity. The human urine samples were provided by the Peking Union Medical College Hospital. All measurements were performed in PB, pH = 6.8, incubated at 35 °C for 40 min. Samples 1~6 are the six different human urine samples with different DOPA concentrations. Meanwhile, the same six human urine samples were also detected by the clinical detection method (HPLC) and the proposed method under the same conditions. From Figure 5D, we can see that the results obtained using the proposed method coincides well with those obtained using HPLC, which indicates that the proposed method can be applied to the detection of DOPA in real samples with a high accuracy.

To evaluate the stability of the C₄N₄-TYR hybrids fluorescent probes, a series of stability experiments were carried out. Figure S5A shows the change of I₀/I when the probes were stored at 4 °C for 100 days. It can be seen that the I₀/I is almost the same during the 100 days at the temperature of 4 °C. As shown in the Figure S5B, the I₀/I is little changed when the fluorescent probes are stored at room temperature for 20 days. These results reveal that the C₄N₄-TYR hybrids fluorescent probes are high stable at the room temperature for low temperature. Based on all of the above experiments and analyses, it can be concluded that, compared with other...
methods, the proposed method not only has excellent repeatability, but also has a wider linear range and presents high accuracy. And it could be successfully applied in detecting DOPA in urine samples. Therefore, more novel biosensors based on the assembly of C4N4 with other enzymes could be expected for the high sensitive detection of other biomolecules and medicament.

Figure 5 (A) DOPA sensing using C4N4-TYR (35 °C, pH=6.8). (B) Relationship between I/I0 and DOPA concentration with DOPA concentration of 1×10^{-6}, 5×10^{-6}, 5×10^{-5}, 1×10^{-5}, 5×10^{-5}, 5×10^{-4}, 1×10^{-4} and 3×10^{-4} mol L^{-1}. The inset is the enlarged graph from 0 to 1.5×10^{-5} mol L^{-1}. (C) Effects of potential interfering substances (35 °C, pH = 6.8). (D) Analytical results of DOPA using the proposed method and using HPLC. The concentrations of DOPA are 3, 9, 16, 21, 27 and 33 μmol L^{-1}, respectively. All measurements were performed in PB, pH = 6.8. The incubation time is 40 min, at 35 °C.

Compared with the detection in liquid phase, it is convenient and fast to do the detection on solid substrate. However, few works have been done on it. To investigate the response of the enzyme-encapsulating C4N4 to DOPA on solid substrate, the enzyme-encapsulating C4N4 sensing arrays on glass slide were performed (Figure 6A). Figure 6A reveals the response of C4N4-TYR to DOPA of different concentrations under room light and UV light (365 nm excitation). It is found that DOPA shows obvious quenching to C4N4-TYR with DOPA concentrations varying from 1×10^{-3} to 2×10^{-1} mol L^{-1}, which indicates that TYR activity in C4N4 is well maintained, and C4N4-TYR sustains its response to DOPA on the glass slide. Furthermore, the response can last for eight weeks without distinct color change. In the following studies, the test papers through the simple chemical method were designed and prepared, which could rapidly and exactly confirm the DOPA concentration range. As shown in Figure 6B, obvious color changes of the C4N4-TYR based test papers containing DOPA with concentration range from 2×10^{-7} to 5.12×10^{-5} mol L^{-1} can be observed under room light and UV light (365 nm, excitation). Clearly, there is distinct fluorescence intensity on the C4N4-TYR modified paper, which was not observed before the modification. Therefore, the immobilized C4N4-TYR on the test paper can retain their fluorescence sensing towards DOPA without the addition of external reagents. Moreover, the sensing can maintain 3 months without obvious change. It can be concluded that C4N4-TYR based test paper provides a practical method to detect DOPA with high sensitivity and stability. To further study the response of C4N4-TYR to DOPA on the test paper, the fluorescence intensities of the reaction system with different DOPA concentrations were recorded. From Figure 6C and 6D, we can see that the fluorescence intensity of C4N4-TYR is obviously quenched in the presence of DOPA on the test paper. Furthermore, good linear correlations are obtained in the concentration range from 1.6×10^{-1} to 2.56×10^{-7} mol L^{-1} for the detection of DOPA on the test paper. (R^2 = 0.995). The detection limit is achieved to 2.56×10^{-7} mol L^{-1}. Based on above results, we can conclude that C4N4-TYR based test paper can serve as high sensitive and reliable sensor for the detection of DOPA.

Figure 6 (A) Photos of the response of C4N4-TYR to DOPA with concentration of 1×10^{-1}, 5×10^{-1}, 2×10^{-1}, 5×10^{-2}, 1×10^{-2}, 5×10^{-2}, 5×10^{-3}, 2×10^{-3} and 0 mol L^{-1} (spots at 7, 5, 2, 1, 0 respectively) under visible light and 365 nm UV light excitation (35 °C, pH = 6.8). (B) Photos of C4N4-TYR impregnated fluorescent test paper sensing DOPA with concentrations of 2×10^{-1}, 4×10^{-1}, 8×10^{-1}, 1.6×10^{-1}, 3.2×10^{-1}, 6.4×10^{-1}, 1.28×10^{-1}, 2.56×10^{-1}, 5.12×10^{-1} and 0 mol L^{-1} (spots 1-10, respectively) under visible light and UV light (365 nm excitation), (35 °C, pH = 6.8). (C) DOPA sensing of C4N4-TYR on the test paper. (D) Relationship between I/I0 and DOPA concentration with DOPA concentration of 1.6×10^{-1}, 3.2×10^{-1}, 6.4×10^{-1}, 1.28×10^{-1} and 2.56×10^{-7} mol L^{-1} on the test paper.

RE1 = Test paper detection vs. Real concentration; RE2 = Test paper detection vs. HPLC clinical detection.

In addition, to verify the efficiency of the C4N4-TYR based test paper, we also applied the standard HPLC method to detect dopamine in simulate human urine sample. Table 1 shows the date obtained in the analysis of simulate human urine sample using the HPLC method and the C4N4-TYR based test paper. It can be seen that the contents of DOPA...
determined using the test paper are consistent with those using HPLC, which exhibits a little relative error. Therefore, it can be concluded that the proposed method is reliable for the determination of DOPA in simulate human urine samples. Meanwhile, it can be expected that the test paper will provide rapid and exact detection for other pharmaceutical and/or biological samples, if the TYR in the C₅N₄ is changed by the other kinds of enzymes.  

**Conclusion**

In summary, a novel detection system containing TYR and C₅N₄ for the sensitive detection of DOPA was designed and fabricated. The fluorescence intensity of the C₅N₄-TYR was significantly quenched as the concentration of DOPA increased, in which a good linear relationship was obtained in the concentration range from 3×10⁻⁸ to 1×10⁻³ mol L⁻¹ with the correlation coefficient of 0.995. Moreover, the easy-to-prepare test paper for convenient and selective detecting DOPA was achieved by using C₅N₄-TYR sensing arrays. The results reveal that the proposed method coincided well with those obtained using HPLC, which indicates that the proposed method can be applied to the detection of DOPA in real clinical samples. The present detection system will provide a new approach to design multifunctional nano-sensors as a new method for the detection of bio-molecules.
