#### Abstract

The quintuply bonded $\left[{ }^{H} \mathrm{~L}^{\mathrm{iPr}} \mathrm{Cr}\right]_{2}$ reacts with various small molecules, revealing a pattern of two kinds of transformations. Unsaturated molecules that are neither polar nor oxidizing form binuclear $[2+n]$ cycloaddition products retaining $\mathrm{Cr}-\mathrm{Cr}$ quadruple bonds. In contrast, polar or oxidizing molecules effect the complete cleavage of the $\mathrm{Cr}-\mathrm{Cr}$ bond.

Occasioned by the discovery of a dinuclear chromium complex featuring a sterically accessible quintuple metal-metal bond, we have begun to explore the reactivity of this novel functional group unique to transition metal chemistry. Recent studies indicate that $\mathrm{M}-\mathrm{M}$ quintuple bonds have a remarkable reaction chemistry. ${ }^{1-16}$ Herein we describe the products of reactions between quintuply bonded $\left[{ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}} \mathrm{Cr}\right]_{2}\left(\mathbf{1}\right.$, where ${ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}}=\mathrm{Ar}-\mathrm{N}=\mathrm{C}(\mathrm{H})-(\mathrm{H}) \mathrm{C}=\mathrm{N}-\mathrm{Ar}$, with $\mathrm{Ar}=2,6$-diisopropylphenyl) ${ }^{17}$ and various small molecules (Scheme 1). These reactions are of interest in their own right and make for fascinating comparisons with the reactivities of other binuclear metal complexes.

1 reacts rapidly with molecules containing multiple bonds. For example, we have previously described [2+2] cycloaddition reactions between $\mathbf{1}$ and alkynes. ${ }^{18}$ While the analogous reaction with ethylene is apparently reversible, $\mathbf{1}$ adds to the destabilized $\mathrm{C}=\mathrm{C}$ double bond of 1,1-dimethylallene, yielding another isolable $[2+2]$ cycloaddition product, namely $\left[{ }_{\left[{ }^{\mathrm{H}}\right.}{ }^{\mathrm{iPr}} \mathrm{Cr}\right]_{2}\left(\mu-\eta^{1}: \eta^{1}-\right.$ $\mathrm{H}_{2} \mathrm{CCCMe}_{2}$ ) (2, see Fig. 1). The terminal $\mathrm{C}=\mathrm{C}$ bond of the allene ligand has added across the two metal centers, forming a fourmembered dimetallacycle. The C53-C54 distance of $1.466(5) \AA$ and the $\mathrm{Cr}-\mathrm{Cr}$ distance of $1.9462(8) \AA$ are consistent with a twoelectron reduction of allene and concomitant oxidation of the $\mathrm{Cr}-\mathrm{Cr}$ center, which, however, retains the short $\mathrm{Cr}-\mathrm{Cr}$ distance characteristic of a quadruple bond (see Table 1). The other $\mathrm{C}=\mathrm{C}$ bond of the allene remains essentially unperturbed (1.346(5) Å).

[^0]

Scheme 1 Reactions of 1 with alkyne, allene, sulfur, $\mathrm{PhN}=\mathrm{NPh}, \mathrm{AdN}_{3}$, CO, benzophenone and benzylideneaniline.

The core of 2 adopts an almost planar geometry with a $(\mathrm{C}-\mathrm{C})-(\mathrm{Cr}-\mathrm{Cr})$ twist angle of $24.3^{\circ}$, similar to the aforementioned alkyne adducts. ${ }^{18}$ The ${ }^{1} \mathrm{H}$ NMR spectrum of 2 exhibited sharp resonances consistent with a diamagnetic ground state of the molecule.

Oxygen atom sources, such as $\mathrm{O}_{2}, \mathrm{~N}_{2} \mathrm{O}$, and NO led to decomposition of 1 accompanied by loss of the diimine ligand. This motivated us to extend the exploration to less oxidizing chalcogens. Thus, treatment of an $\mathrm{Et}_{2} \mathrm{O}$-toluene solution of 1 with elemental sulphur, at room temperature, caused the initially green solution to turn deep blue. A standard work-up of the reaction and recrystallization from diethyl ether yielded the simple binuclear adduct, $\left[{ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}} \mathrm{Cr}\right]_{2}\left(\mathrm{~S}_{2}\right)(3)$ in modest yield (20\%). The molecular structure of 3 is depicted in Fig. S1 (ESI $\dagger$ ); it features a four-membered $\mathrm{Cr}_{2} \mathrm{~S}_{2}$ ring. The "supershort" ( $\mathrm{Cr}-\mathrm{Cr}<2.0 \AA$ ) $\mathrm{Cr}-\mathrm{Cr}$ bond of $3(1.9305(8) \AA$ ) is appreciably longer than that in $\mathbf{1}$ (1.8028(9) $\AA$ ), indicating an oxidation from $\mathrm{Cr}(\mathrm{I})$ to $\mathrm{Cr}(\mathrm{II})$ and hence a bond order reduced to 4 . The S-S bond length of $2.0513(10) \AA$ approximates that of Kempe's disulfide analog (2.058(4) $\AA$ ), ${ }^{2}$ which, however, features perpendicular coordination of the $\mathrm{S}_{2}{ }^{2-}$ unit and that of $\mathrm{Cp}_{2} \mathrm{Cr}_{2}(\mu-\mathrm{S})_{2}\left(\mu-\eta^{1}-\eta^{1}-\mathrm{S}_{2}\right)(2.028(2) \AA)^{19}$ As is typical of the [2+2] cycloaddition products of $\mathbf{1}$, the $\mathrm{Cr}_{2} \mathrm{~S}_{2}$ core is not perfectly planar. The ( $\mathrm{S}-\mathrm{S}$ )-( $\mathrm{Cr}-\mathrm{Cr}$ ) twist angle for the core is $15.6^{\circ}$, somewhat smaller than the analogous angles in the alkyne adducts and 2.

Table 1 contains selected bond lengths and angles for compounds 2-7. All the 'cycloaddition' products of $\mathbf{1}$ that maintain $\mathrm{Cr}-\mathrm{Cr}$ bonds, i.e. 2, 3, and 1-2-butyne, exhibit the twisted $\mu-\eta^{1}: \eta^{1}$ bonding mode for the $X_{2}$ ligands ( $\mathrm{X}=\mathrm{C}, \mathrm{S}$ ); this differs from the perpendicular (i.e. $\mu_{2}-\eta^{2}: \eta^{2}$ ) bonding motif more typically observed for complexes with metal-metal bonds, e.g. in Kempe's aminopyridinato dichromium complexes. ${ }^{2-4,20}$ At the same time, the dihedral angles ( $\delta$ ) between the $\alpha$-diimine ligand planes are significantly larger than those of the aminopyridinato complexes (e.g. $107^{\circ}$ for both the disulfide and the tolylacetylene adduct). In other words, the $\left[\mathrm{L}_{2} \mathrm{Cr}_{2}\right]$ fragments of the $\alpha$-diimine complexes are considerably flatter than those with aminopyridinato ligands. The near preservation of the planar geometry of $\mathbf{1}$ and the formation of unsaturated fourmembered $\mathrm{Cr}_{2} \mathrm{X}_{2}$ rings as opposed to tetrahedrane-like structures is unlikely to be steric in origin. An electronic explanation may be rooted in the electronic flexibility afforded by the redox-active $\alpha$-diimine ligands; this remains to be explored.

An isoelectronic - but less oxidizing - analog of $\mathrm{O}_{2}$ is azobenzene $(\mathrm{PhN}=\mathrm{NPh})$. When one equivalent of the latter

Fig. 2 The molecular structure of $\mathbf{4}$ and $\mathbf{5}$ (both at $30 \%$ probability level).
was added to a solution of $\left(\mu-\eta^{1}: \eta^{1}-{ }_{-} \mathrm{L}^{\mathrm{iPr}}\right)_{2} \mathrm{Cr}_{2}$ (1) in diethyl ether, subsequent work-up and recrystallization produced redbrown crystals of dinuclear complex $\left[{ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}} \mathrm{Cr}(\mu-\mathrm{NPh})\right]_{2}$ (4) in $40 \%$ isolated yield. 4 is a dinuclear complex with bridging imido ligands (Fig. 2, top). This reaction may well go through an unstable [2+2] cycloaddition intermediate, which suffers oxidative addition, due to the high electronegativity of nitrogen. The molecular structure of $\mathbf{4}$ features four-coordinate chromium (ignoring the rather long $\mathrm{Cr}-\mathrm{C}$ interactions) adopting pseudotetrahedral geometry, which is the preferred geometry of 4 -coordinate $\operatorname{Cr}(\mathrm{III})$. The $\mathrm{N}=\mathrm{N}$ double bond has been severed completely $\left(N \cdots N_{\text {avg }}=2.695 \AA\right.$ ). Similarly, the distance between the two chromium atoms in 4 is 2.498(4) $\AA$, indicating the absence of any significant bonding interactions.

The average bond lengths of $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{N}$ bonds in the backbone of the $\alpha$-diimine ligand are $1.395(11)$ and $1.380(9) \AA$, characteristic of a diimine radical anion; accordingly, chromium is in the formal oxidation state + III $(S=3 / 2)$. The effective magnetic moment of 4 at room temperature was $2.4(1) \mu_{\mathrm{B}}$, consistent with antiferromagnetic coupling, both between the metal and its radical ligand as well as between the chromium atoms.

The reaction between $\left(\mu-\eta^{1}: \eta^{1}-{ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}}\right)_{2} \mathrm{Cr}_{2}$ (1) and sterically demanding $\mathrm{Ad}-\mathrm{N}_{3}$ afforded another imido complex, namely
$\left[{ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}} \mathrm{Cr}\right]_{2}$ (NAd) (5), as shown in Fig. 2 (bottom). Only one imido group has been added across the $\mathrm{Cr}-\mathrm{Cr}$ bond. Once again, we suggest that a five-membered [2+3] cycloaddition product may be formed first, which rapidly extrudes $\mathrm{N}_{2}$. The bond distances and angles of $\mathbf{5}$ are comparable to those of other known bridging imido complexes of chromium. ${ }^{22-26}$ Similar to the geometries of the $[2+2]$ cycloaddition products, the elongated $\mathrm{Cr}-\mathrm{Cr}$ distance of $1.9575(11) \AA$ is consistent with the twoelectron oxidation of the $\mathrm{Cr}_{2}$ unit (to $\mathrm{Cr}(\mathrm{II})$ ). 5 is also diamagnetic, presumably due to metal-metal quadruple bonding.

Finally, we were interested in studying the reactivity of 1 toward unsaturated molecules featuring $\mathrm{X}-\mathrm{Y}$ bonds $(\mathrm{X}, \mathrm{Y}=\mathrm{C}, \mathrm{N}, \mathrm{O})$. Exposure of a benzene solution of $\mathbf{1}$ to $\mathrm{CO}(1 \mathrm{~atm})$ produced the dark blue carbonyl ${ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}} \mathrm{Cr}(\mathrm{CO})_{4}$, as confirmed by ${ }^{1} \mathrm{H}$ NMR spectroscopy. ${ }^{21}$ The reaction of 1 with benzophenone resulted in dinuclear $\left[{ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}} \mathrm{Cr}\left(\mu-\mathrm{OPh}_{2}\right)\right]_{2}$ (6). The structure of 6 (shown in Fig. S2, ESI $\dagger$ ) reveals a benzophenone-bridged dimer with square planar Cr centers. The average carbon-oxygen bond length of the benzophenone is $1.355(5) \AA$, which is much longer than the $1.230(3) \AA$ in benzophenone, ${ }^{27}$ suggesting some degree of reduction of the $\mathrm{C}=\mathrm{O}$ bonds. The average bond lengths of $\mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{N}$ bonds of the backbone of the $\alpha$-diimine ligand are 1.360(6) and 1.336(6) $\AA$, consistent with those of a monoanionic diimine ligand. ${ }^{21}$ These structural features suggest that 6 is a $\operatorname{Cr}(\mathrm{II})$ complex. Like $\left[{ }^{\mathrm{H}} \mathrm{L}^{\mathrm{iPr}} \mathrm{Cr}(\mu-\mathrm{Cl})\right]_{2},{ }^{17} 6$ exhibited a simple isotropically shifted and broadened ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{C}_{6} \mathrm{D}_{6}$, with chemical shifts at 96 , $14.6,3.2,1.56$, and -13.0 ppm . $\mu_{\mathrm{eff}}(\mathrm{RT})$ of this complex was found to be $5.1(2) \mu_{\mathrm{B}}$ (3.6(1) $\mu_{\mathrm{B}}$ per chromium), which is consistent with two antiferromagnetically coupled $\operatorname{Cr}(\mathrm{II})$ metal centers ( $S=2$ ) coordinated by ligand radicals ( $S=1 / 2$ ).

In contrast to $\mathbf{6}$, reductive coupling of $\mathrm{C}=\mathrm{N}$ double bonds was observed upon exposure of $\mathbf{1}$ to four equivalents of transbenzylideneaniline. The reaction was found to form the coupling product, ${ }^{H}{ }^{\mathrm{L} P r} \mathrm{Cr}\left(\kappa^{2}-\mathrm{N}_{2} \mathrm{C}_{26} \mathrm{H}_{22}\right)$ (7). The crystal structure is shown in Fig. 3. 7 adopts tetrahedral coordination about chromium

Fig. 3 The molecular structure of $\mathbf{7}$ ( $30 \%$ probability level).
with the $\alpha$-diimine apparently being in the singly reduced state (see Table 1). The room temperature effective magnetic moment of 7 was found to be $2.9(1) \mu_{\mathrm{B}}$, consistent with a $\mathrm{Cr}($ III $)$ metal center $(S=3 / 2)$ strongly coupled to a ligand radical $(S=1 / 2)$.

In summary, reactivity studies on a quintuply bonded dichromium complex supported by $\alpha$-diimine ligands have been extended to a variety of molecules. The products are varied and their structures differ from those established for quintuply bonded complexes supported by other ligands. A pervasive feature of 1 seems to be the formation of $[2+n]$ cycloaddition products with nonpolar substrates. Polar, heteroatomic multiple bonds on the other hand effect complete cleavage of the metal-metal bond.
