Micro–nanomotors (MNM)s are micro/nanoscale intelligent devices with vast potential in the fields of drug delivery, precision medicine, biosensing, and environmental remediation. Their primary advantage lies in their ability to convert various forms of external energy (such as magnetic, ultrasonic, and light energy) into their own propulsive force. Additionally, MNMs offer high controllability and modifiability, enabling them to navigate in the microscopic world. Importantly, recent research has harnessed the unique advantages of MNMs to synergize their capabilities in neuromodulation. This mini-review presents the significant progress and pioneering achievements in the use of MNMs for neuromodulation, with the aim of inspiring readers to explore the broader biomedical applications of these MNMs. Through continuous innovation and diligent exploration, MNMs show promise to have a profound impact on the field of biomedicine.

1 Introduction

The film *Fantastic Voyage* released in 1966 vividly shows a microsubmarine sailing through blood and treating diseases, attracting worldwide researchers to focus on the research of micro- and nanoscale machineries. Half a century later, the Nobel Prize in Chemistry 2016 was jointly awarded to Jean-Pierre Sauvage, Fraser Stoddart and Ben Feringa for their pioneering contributions in the field of molecular machines.¹ Inspired by molecular machines and benefitting from the rapid advancement of nanotechnology,^{2,3} various micro/nanomotors have been developed, which can convert chemical

energy and other energy into mechanical energy at the micro/nanoscale, enabling them to move in a directional manner through their asymmetric structure, thereby performing more complex tasks.⁴

Micro/nanomotors, also known as micro/nanomachines, micro/nanorobots and micro/nanoswimmers, are generally tens of nanometers to tens of micrometers in size, and many researchers have worked on using various ways to make them move. Because the Reynolds number of MNMs in water is extremely low, driving such a tiny device is a laborious task. In this case, the motion of motors is completely dominated by viscous force, which is similar to one swimming in a pool full of viscous syrup.⁵ Due to the time reversal symmetry of a low Reynolds number fluid, many macro-feasible propulsion methods are not applicable,^{6,7} such as breaststroke. Therefore,

Yulin Huang

Yulin Huang is now studying in the School of Materials Science and Engineering, Sun Yat-sen University, under the guidance of Professor Fei Peng. Presently, he is engaged in research on micro/nanomotors for neuromodulation.

Fei Peng

Dr Fei Peng obtained his PhD from Radboud University Nijmegen in the Netherlands. In 2017, she joined Sun Yat-sen University and was appointed as a “Hundred Talents Program” associate professor in the School of Materials Science and Engineering. She was supported by Guangdong Provincial Distinguished Youth Funding and the National Natural Science Foundation of China. Her research group focuses primarily on self-driving nanomotors for biomedical applications.

scientists have developed some novel propulsion mechanisms to drive MNMs. These mechanisms can be divided into two categories: (1) self-propulsion: achieved by creating an asymmetric field around the motor using chemical or physical reactions to induce fluid flow or by generating bubbles and direct mechanical forces to propel the motor. Self-propulsion can be subdivided into bubble propulsion,^{8–12} self-electrophoresis,^{13–15} self-diffusiophoresis,^{16–19} self-thermophoresis^{20–23} and biological agent propulsion (directly utilizing natural motile microorganisms to drive motors, such as bacteria or spermatozoa).²⁴ (2) External propulsion: utilizing external energy for propulsion, including light, electricity, ultrasound, and particularly magnetic field,^{25,26} which is regarded as a facile method for clinical settings. Among these driving mechanisms, a common idea is to make physical or chemical reactions occur asymmetrically on the motor to generate uneven forces to propel itself.

Thanks to their ultra-small size, micro/nanomotors can perform operations in the microscale that cannot be reached by traditional devices, so they have a particularly profound impact on biomedicine.^{27,28} For instance, MNMs can be employed in microfluidic chips for micromanipulation,^{29,30} they can navigate in the natural lumen of an organism for medical imaging,^{31–33} and they can even have potential as label-free biomechanical probes.^{34,35} MNMs can also work together, and one can control the MNM groups and reach the target to release drugs.^{36,37}

In the past few years, with the vigorous development of micro/nanomotors, reviews on different applications of motors have sprung up, which reflects researchers' enthusiasm for more extensive application of MNMs. In recent years, our research group has revealed the immense potential of MNMs in neuromodulation, but this function has not attracted enough attention in industry. It is time to summarize the current research progress of MNMs in neuromodulation, which have not been reviewed yet.

2 Micro/nanomotors for neuromodulation

Neuromodulation refers to biomedical engineering technologies that utilize invasive or non-invasive techniques to modulate the activity of the nervous system through physical or chemical stimulus, resulting in specific functions.³⁸ The development of neuromodulation techniques is not only an important pathway for basic neuroscience research, but also an effective option for treating neurological disorders, such as Alzheimer's disease, gastrointestinal diseases, Parkinson's disease, muscle tension disorders, obsessive-compulsive disorder, *etc.*

Micro/nanomotors as emerging tools for non-invasive neuromodulation, have begun to receive attention from researchers due to their advantages of limited trauma and low cost.³⁹ According to different mechanisms, MNMs for neuromodulation are divided into two categories in this article:

chemical and physical pathways. The two have a common characteristic that they actually have the ability of nerve stimulation through direct electrical activation of the corresponding ion channels (such as thermosensitive ion channels, mechanosensitive ion channels, and specific ion channels activated by reactive oxygen species), making them particularly suitable for the treatment of neurological related diseases, which will be elaborated in the following sections.

2.1 Physical pathways

Physical stimulation (mechanical, thermal, acoustic, optical and electrical stimulus) is the most traditional neuromodulation option.⁴⁰ In this section, we summarized the applications of cross-modal neuromodulation (such as magnetism-electric and ultrasonic-electric synergistic stimulation). It is worth noting that considering the long history and wide application of electrical stimulation, we present detailed introductions to self-established electricity and piezoelectric effects here. However, besides utilizing electricity, mechanical stimulation, thermal stimulation, and non-thermal stimulation using mid-infrared light have also been emerging neuromodulation methods in recent years.

2.1.1 Self-established electricity. The role of electrical stimulation in the field of neural regulation cannot be ignored. It can be traced back to ancient Egypt, which shows its long history. People first directly observed the regulation of brain function by applying weak direct current in the early 19th century. And in the past decade transcranial magnetic stimulation and deep brain stimulation have been clinically transformed and used worldwide, providing alternatives for treating neurological and neuropsychiatric diseases.⁴¹ However, many studies have shown that the structural and mechanical differences between traditional invasive electronic devices and their neuronal targets may lead to the destruction of natural tissues, thus preventing the device from conducting neuromodulation steadily over time.^{42–44} Moreover, batteries required by the devices generally have large volume and short lifetimes. What is more serious is that replacing the battery and the corresponding surgery increase the economic burden and risk for patients.⁴⁴ The shortcomings of invasive devices in energy supply have limited their progress.⁴⁵ Therefore, it is of great significance to develop a power supply independent device.

One approach to addressing the reliance on wired power supply is by utilizing the self-generated electric field produced by micro/nanomotors (MNM). To this end, our research group has developed a water-driven Ni-Zn tubular MNM capable of magnetically controlling its direction for the purpose of directional differentiation of neural stem cells.⁴⁶ The aim of this study is to propose new treatment strategies for neurodegenerative diseases such as Alzheimer's disease and Parkinson's disease. The motor is fabricated using the electrochemical deposition method and serves as a typical representative of metal-based micro/nanomotors.⁴⁷ The motor's motion mechanism primarily relies on the reaction between the Zn segment and water: $\text{Zn} + 2\text{H}^+ \rightarrow \text{Zn}^{2+} + \text{H}_2$,

which increases the concentration of Zn^{2+} ions in the zinc segment, consequently creating a self-generated electric field towards the Ni segment and inducing the motor's movement towards the Zn segment. It is noteworthy that the motion of the motor does not generate any bubbles. Consequently, when compared to previous chemically driven micromotors, the likelihood of gas blockage is eliminated. Under magnetic field control, the motor can achieve an average speed of $27.7 \pm 1.5 \mu\text{m s}^{-1}$ in deionized water. Leveraging its self-propulsion and directional capability, motors can reach the region where endogenous neural stem cells reside, facilitating the exchange of bioelectric signals and intracellular communication with neural stem cells through the self-generated electrochemical fields. As a result, the neural stem cells can undergo differentiation into neurons. *In vitro* experiments involving the cocultivation of the motor and neural stem cells have shown significant differentiation of neural stem cells into neurons. Furthermore, *in vivo* experiments have provided evidence of the ability of the motor to guide neuronal regeneration. This study offers compelling evidence of the neuronal regeneration capabilities exhibited by micro/nanomotors, unveiling new possibilities for exploration in the field of minimally invasive precision medicine (Fig. 1).

Additionally, our research group has also conducted other in-depth studies on the use of self-generated electricity for neural stimulation. For example, we have successfully developed motors based on Au-TiO₂ and explored their application in modulating neuronal activity. Firstly, we synthesized the TiO₂-Au-nanowire-based motor,⁴⁸ which converts ultraviolet light energy into mechanical motion through photoelectric conversion, achieving highly controllable movement in a bio-

logical environment. By locally generating electric fields, motors were able to activate calcium ion channels and achieve precise manipulation and regulation of individual neurons. In addition to using MNMs for neural stimulation of individual neurons, the collective behavior of nanomotors has also intrigued us in the field of neuromodulation. Therefore, we further described the black (B)-TiO₂@N/Au nanorobots.⁴⁹ The main purpose of studying this motor is to explore collective intelligent systems that effectively interact with biological entities. When these nanomotors were exposed to program controlled near-infrared (NIR) light, they showcased periodic swarming oscillation behavior due to electrophoresis induced by photolytic water decomposition. It has been discovered that this oscillating electrochemical field leads to the activation of nearby neurons *in vitro* and triggers resonant oscillation of neural populations without any synaptic contact. This research explores the connection between oscillating nanomotor populations and biological rhythms, particularly neuronal activity, while effectively demonstrating the stability and biocompatibility of the nanomotor populations in various cellular environments. Ultimately, the significance of this research lies in the innovative collective resonant nanomotors which facilitate the transmission of neural signals beyond the millimeter scale, thus offering fresh and practical avenues for regulating neural activity and information transmission. Moreover, these findings have potential to contribute to the advancement of bioelectronics by providing valuable insights and potential applications (Fig. 2).

It is essential to acknowledge that, despite significant progress being made in *in vitro* and animal experiments, there are still many obstacles to overcome on the path to clinical conversion. One such challenge involves the programmability of electric fields, which is critical for effective implementation.^{50,51}

2.1.2 Piezoelectric effect. The piezoelectric effect operates on the principle that applying pressure to a piezoelectric material results in the generation of a potential difference, known as the positive piezoelectric effect. Conversely, the application of voltage induces mechanical stress, which is referred to as the inverse piezoelectric effect. In other words, piezoelectric materials possess the ability to convert and interchange mechanical and electrical energy. This intrinsic correlation between the two phenomena is intriguing, and as a result, piezoelectric devices find extensive utility in the realm of neural regulation.^{52,53} Researchers have proposed the use of micro/nanomotors with piezoelectric properties as promising solutions to mitigate the tissue trauma caused by traditional devices, enhance spatiotemporal accuracy and therapeutic efficacy, and facilitate further miniaturization.⁵⁴

BaTiO₃ is a piezoelectric material with a long history. As early as the 1950s, it was regarded as a promising candidate for applications in piezoelectric transducers.⁵⁵ In recent years, it has emerged as a viable alternative to lead zirconate titanate [Pb(Zr,Ti)O₃(PZT)], which is the most widely used piezoelectric ceramic material in the fields of neural modulation and neural tissue engineering. This substitution aims to mitigate the severe toxicity associated with lead.⁵⁶ Our research group pro-

Fig. 1 The schematic diagram illustrating the motion behavior of Ni-Zn micromotors, targeted activation and directed cell differentiation of NSCs. This figure has been reproduced from ref. 46 with permission from John Wiley and Sons, copyright 2023. The Ni-Zn micromotor approach targets NSCs under magnetic guidance. With a self-generated chemical electric field, the micromotors further activate voltage-gated ion channels in the cells, thus guiding the differentiation fate of the target NSCs.

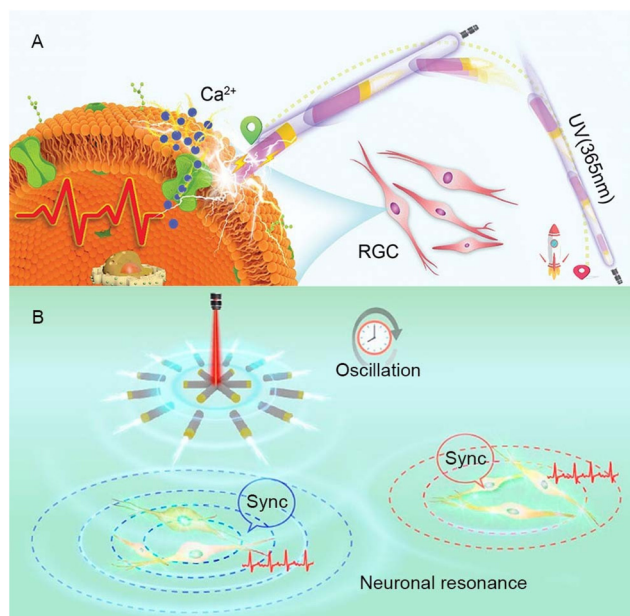

Fig. 2 (A) TiO_2 -Au nanowire-based motors are capable of targeting neuronal retinal ganglion cells under ultraviolet irradiation. They generate electricity transmitted as a signal to the target cells and trigger cell activation. posed a strategy that combines the piezoelectric effect of BaTiO_3 with micro/nanomotors for neural stem-like cell stimulation. To this end, we have designed and fabricated a magnetic and piezoelectric nanomotor, denoted as $S. platensis@Fe_3O_4@tBaTiO_3$, which serves as a highly controllable platform for neural stem cell stimulation.⁵⁷ The preparation of this nanomotor involved the coating of Fe_3O_4 and $BaTiO_3$ nanoparticles onto *S. platensis*. The Fe_3O_4 component endows the nanomotor with the capability to autonomously migrate towards the target neural stem cell position under the influence of a magnetic field. And $BaTiO_3$ exhibits the property of converting ultrasonic energy into electrical signals, thereby inducing the differentiation of the desired target cells. The research team has further investigated the functionalities of the nanomotor. By varying the intensity of ultrasonic stimulation, neural stem cells can be directed by the nanomotor to differentiate into astrocytes, functional neurons, and oligodendrocytes.⁵⁸ Notably, our study also demonstrates the differentiation of neural stem cells into dopamine neurons and cholinergic neurons, offering potential remedies for disorders associated with the degeneration of these specific neuron types (Fig. 3).

In general, piezoelectric micro/nanomotors have broad prospects for applications in the field of neuroscience. Other piezoelectric materials, such as molybdenum disulfide (MoS_2), have recently been reported as adjustable artificial synapses,

Fig. 3 The schematic diagram depicting the assembly of $S. platensis@Fe_3O_4@tBaTiO_3$ micromotors, and the motors precisely stimulate the differentiation of neural stem cell-like cells under magnetic driving. This figure has been adapted from ref. 57 with permission from John Wiley and Sons, copyright 2020.

providing new inspiration for the development of more piezoelectric micro-nanomotors.⁵⁹ However, there are still some issues in research that cannot be ignored, such as the biocompatibility of piezoelectric materials in synergy with MNMs. Taking the classic piezoelectric material zinc oxide nanoparticles (ZnO NPs) as an example, although ZnO NPs were previously considered to have low toxicity, recent research has reported various toxicities and mechanisms of ZnO NPs.⁶⁰ In addition, ultrasound, as the signal to trigger the piezoelectric effect in MNMs, may face attenuation issues inside the human body. Nevertheless, excessive increase in ultrasound intensity may lead to side effects such as excessive thermal and ultrasonic cavitation effects.

In addition to nerve regulation through electricity, other physical stimulation has expanded the toolkit and provided valuable inspiration for subsequent research. Regarding thermal stimulation, recent research by Wu *et al.* utilized infrared light within the 400–1800 nm range to implement deep brain stimulation in mice *via* the photothermal conversion of nanoparticles.⁶¹ However, given the limitations associated with using light-thermal stimulation, a growing number of researchers are turning their focus towards non-thermal methods of nerve stimulation. For instance, Wu *et al.*³⁴ developed nanoparticles that directly employ blue light excited by near-infrared light for neuronal stimulation, taking an important step towards non-invasive deep brain stimulation.⁶² Furthermore, mechanically sensitive ion channels have received much interest. Collier *et al.* designed a magnetically-driven magnetic microdisk (MMD) with a diameter of 4 μm and thickness of 100 nm for activating hippocampal neurons and cortical neurons, showcasing high efficiency and prolonged stimulation characteristics.⁶³

2.2 Chemical pathways

Not only in the field of micro/nanomotors, previous research has devoted an excessive amount of attention to the appli-

cation of electrical stimulation in the field of neuromodulation. The majority of commercially available neuromodulation methods rely on electrical stimulation, while current studies on neuromodulation using chemical approaches primarily concentrate on drug design or passive targeting strategies utilizing nanoparticles.⁵⁴ Therefore, there is a need for increased focus on actively targeted neuromodulation methods that involve principles of chemistry.

Reactive oxygen species (ROS) have a significant impact on the nervous system. ROS is a natural byproduct of oxygen metabolism and plays crucial roles in cell signaling and homeostasis. ROS have been demonstrated to activate particular ion channels, including the mammalian transient receptor potential (TRP) channels.⁶⁴ Significantly, the ROS and calcium pathways have the ability to interact,⁶⁵ rendering them suitable for neural regulation. However, exposure to environmental pressures such as ultraviolet radiation, heat, and trauma can cause a sharp increase in ROS levels, leading to severe damage to cell structures, which is known as oxidative stress.⁶⁶ Numerous researchers in the field of micro/nanomotors are dedicated to counteracting ROS *via* various strategies to minimize their harmful effects on the nervous system.^{67–69} Interestingly, ROS generation can also be harnessed to eliminate proteins responsible for neurodegenerative diseases in the nervous system.^{70–72} Due to the effects of ROS on normal cells including oxidative stress and carcinogenic risk, many ROS probes have been developed to prevent damage to normal tissues. In addition, methods for regulating ROS concentration have also emerged. For example, Sun's team developed a titanium oxide electrocatalyst,⁷³ which promotes ROS generation at low ROS concentrations but exhibits inhibitory effects at high concentrations. It can be expected that this technology can be applied in the field of micro/nanomotors, such as for photodynamic therapy and neural modulation. However, due to the complexity of ROS composition, it remains a challenge to be addressed for biomedical applications of ROS. This section aims to present recent research trends over the past three years and elucidate the extensive development possibilities of ROS as a typical chemical neuromodulation approach, in combination with MNMs.

2.2.1 Neutralizing ROS for nerve injury repair. Traumatic brain injury (TBI) refers to the damage to soft tissues, skull bones, and brain tissues caused by mechanical forces, and is a serious public health and socio-economic issue worldwide. The secondary injuries resulting from neurochemical and metabolic changes include acute oxidative stress, inflammatory reactions, and blood–brain barrier dysfunction. These secondary injuries may occur within minutes to hours after the injury, leading to neuronal death and irreversible neurological dysfunction.⁷⁴ Therefore, there is an urgent need to develop a feasible solution for the rapid management of life-threatening emergencies until commencement of hospital treatment. Currently, there are very few expedient interventions available for brain injuries, and secondary brain injuries are difficult to reverse with subsequent surgical and medical treatments such as dehydration agents, neuroprotective drugs, and hemostatic drugs for treating brain edema.⁷⁵

To address this, Xue's team proposed Janus catalysis-driven nanomotors (JCNs) using a plasma-induced alloying technique and sputtering-caused half-coating strategy, successfully solving the challenge of rapid and deep penetration into brain tissue.⁶⁸ Theoretical calculations and experimental results demonstrate that heteroatom-doped alloy engines endow JCNs with higher catalytic activity in the removal of reactive oxygen species (ROS) and reactive nitrogen species (RNS) compared to common Pt-based motors. When JCNs are dropped onto the surface of a fractured skull, they effectively catalyze endogenous hydrogen peroxide, as fuel to promote JCNs to infiltrate deep brain injuries. This allows for further nanocatalyst-mediated cascade-blocking therapy to clear ROS and RNS, such as hydroxyl radicals, superoxide radicals, and peroxy-nitrite ions. Ultimately, JCNs reversed various behavioral impairments and significantly reduced the mortality rate of mice with sTBI. In summary, this work provides a revolutionary nanomotor-based strategy for sensing brain injuries and clearing oxidative stress, demonstrating significant therapeutic potential in assisting emergency TBI.

In addition, spinal cord injury (SCI) is an external trauma that brings heavy physical and economic burden to patients. The pathological process of SCI is complex, and once it occurs, it leads to the loss or severe impairment of motor, sensory, and autonomic functions.^{76,77} The existence of the blood–spinal cord barrier (BSCB) creates challenges in facilitating the access of numerous drugs employed for SCI treatment to the specific site of spinal cord injury. Consequently, the selection of an effective drug delivery system to improve treatment outcomes has become a hot topic in current research.

Recently, Mao and Wan's research group have provided a new strategy for treating SCI through the design of a poly(2-methacryloyloxyethyl phosphorylcholine) (PMPC)/L-arginine (PMPC/A)-based nanomotor.⁶⁷ This nanomotor can release nitric oxide (NO), load the nerve growth factor (NGF), and inducible nitric oxide synthase inhibitor 1400W. With its high drug loading capacity and strong ability to penetrate pathological tissues, it shows great potential in SCI treatment. Researchers have also discovered that this nanomotor can lower oxidative damage and inhibit the expression of nitric oxide synthase by regulating the levels of ROS, leading to the suppression of inflammatory reactions. Additionally, the nanomotor can effectively penetrate the BSCB, then by regulating the internal environment and releasing therapeutic drugs, restore the motor function in a rat SCI model (Fig. 4).

These studies have demonstrated the potential of MNMs in the treatment of acute neurological disorders. They provide new ideas for developing novel therapeutic strategies, improving treatment efficiency, and shortening treatment duration. However, these studies are still in the laboratory stage and require further clinical research and validation to ensure safety and efficacy.

2.2.2 Utilizing ROS for pathogenic protein clearance. It should be noted that ROS are not only eliminated as harmful substances but are also utilized in specific contexts to clear pathological protein aggregates, which serve as crucial

Fig. 4 JCNs decompose excessive ROS to generate an asymmetric pressure wave to propel themselves forward, and the decomposition of ROS can also block the inflammatory cascade reaction induced by oxidative stress, thus preventing secondary damage to brain tissues. This figure has been reproduced from ref. 68 with permission from John Wiley and Sons, copyright 2022.

markers for various neurodegenerative diseases. The conventional method for targeted therapy of neurodegenerative diseases primarily relies on the utilization of non-autonomous nanoparticles to disassemble protein fibers, yet the outcomes have proved to be unsatisfactory.⁷⁸

To enhance the dissociation effect, the Mayorga-Burrezo team has designed a light-driven micromotor based on concave BiVO₄ microspheres.⁷⁰ Experimental results demonstrate that this micromotor can generate reactive ROS, such as superoxide radicals and hydroxyl radicals, to induce protein fiber disaggregation. The study also reveals that the helical trajectory of the motor enhances this effect through the uniform distribution of ROS. This motor not only exhibits great potential in dismantling protein fibers, but also has the potential to be extended to photodynamic therapies, such as lung cancer or skin cancer, which can utilize ROS for treatment. This work provides crucial insights into the application of novel strategies in the treatment of neurodegenerative disorders, filling a

Fig. 5 L-Arginine loaded on PMPC/A/1400W/Nfif nanomotors can react with reactive oxygen species in the injured neural microenvironment to produce NO, thereby propelling the motors. gap in the application of MNMs for protein fibril disaggregation.

Although this is an exciting new discovery, the detrimental impact of ROS on normal tissues cannot be disregarded. Elevated ROS levels can lead to damage in proteins, lipids, and DNA, resulting in oxidative stress and ultimately contributing to the development of neurodegenerative diseases.⁷⁹ In addition, the potential adverse effects of ROS produced by MNMs on cells or animals have not been definitively established, creating a controversial issue. Therefore, it is imperative to precisely regulate the concentration range of ROS generation to ensure that it does not induce severe consequences while effectively eliminating pathological proteins. Furthermore, Hajipour *et al.* propose that shorter fibrils generated after nanoparticle disaggregation may exhibit more potent pathogenic effects compared to longer fibrils. This observation could be attributed to their smaller size and increased mobility, enabling them to insert and disrupt membrane environments.⁸⁰ As a result, the traditional assumption that protein fibril dissolution will lead to laxation in Alzheimer's disease must be reevaluated. It is important to acknowledge that while this research presents a groundbreaking application, there is still a long way to go before clinical implementation and it requires further efforts (Fig. 5).

3 Conclusions and outlook

The field of micro/nanomotors has witnessed significant advancements, leading to the development and application of motors with diverse mechanisms and structures in various bio-

medical scenarios. Despite these advancements, there remain untapped potential areas that are suitable for exploration. Thus, this article aims to review representative emerging examples of MNMs in the field of neuromodulation within the last three years, shedding light on their applications in this field. As a newly emerging application scenario in recent years, neuromodulation demonstrates the revolutionary potential of MNMs in the field of nanoscience for practical applications. Science is limitless, and we believe that in addition to the several mechanisms mentioned in this minireview, more physical or chemical properties proposed in fundamental research on MNMs will be applied to neuromodulation. We discuss the challenges faced by this field and its future development direction in this section in order to provide new inspiration for relevant researchers and urging attention to conflicts in upstream theories in future research. This is the purpose of this minireview.

(1) The advantages revealed by MNMs serve as a source of inspiration for this field. MNMs possess a high spatial resolution due to their minuscule size, enabling precise stimulation of neurons through accurate positioning. This characteristic is particularly beneficial for achieving high spatial resolution in neuroregulation with the use of piezoelectric nanomotors. MNMs share the strengths of non-invasiveness, controllability, and multifunctionality. Compared with traditional methods of electrical or chemical stimulation, the use of MNMs is less invasive, minimizing damage to tissues and neurons. By modifying the shape, size, and composition of motors, the properties and intensity of piezoelectric effects can be controlled, facilitating various modes of neuromodulation to meet the diverse requirements and provide customized treatment approaches. Furthermore, the mechanisms of MNMs are often not singular, which is known as cross-modal neuromodulation, further augmenting their multifunctionality.⁵⁴ This attribute positions MNMs as a highly promising tool for neuromodulation, capable of selectively exerting their effects in different application scenarios.

(2) Focus is required on the challenges currently faced in the field of micro/nanomotors and further promoting their practical biomedical applications. Biocompatibility is a crucial consideration, as studies have shown that nanomaterials can induce adverse effects such as immune reactions, cell toxicity, and inflammatory responses. Safety is paramount when utilizing MNMs for neuromodulation due to the sensitivity and significance of the nervous system. For the biocompatibility of neurobiological materials, it is required that the material has no adverse effects on neurons during degradation. In addition to the toxicity during the degradation process, in terms of physical compatibility, materials in contact with nerves need to be compatible biomechanically, otherwise inflammatory reactions can be induced.⁸¹ However, several factors persist regarding the potential long-term risks of MNM utilization in the nervous system, including the stability, distribution, and metabolic pathways of nanoparticles. Additionally, the lack of standardization and regulation hampers the progress of research and applications in the field of neural modulation

using MNMs. Conducting more comprehensive investigations to determine the optimal dosage, actuation duration, frequency, and other parameters of nanomotors is essential to ensure the feasibility of practical implementations. Subsequent research should give priority to addressing these challenges to promote the further development and application of MNMs in neural modulation.

(3) Attention to current upstream research enables the discovery of new possibilities for nanomotors. For instance, significant advancements have been achieved in optogenetics involving model organisms like *Caenorhabditis elegans*, which are relevant to neuromodulation.^{82,83} In addition, there is a long research history on related nanoparticles, such as upconversion nanoparticles (UCNPs).^{84,85} However, the spatiotemporal accuracy of these nanoparticles is hindered by the scattering of light in biological tissues and their inadequate targeting efficiency. MNMs offer potential solutions to address this issue. It is crucial to acknowledge that genetic modifications necessary for this technology continue to be constrained within human and non-human primate species, resulting in a challenging path towards clinical trials.

In the past two decades, we have witnessed the emergence of the first micro/nanomotor and its rapid proliferation, showcasing its value in addressing various complex problems. In the future, with the close integration of medicine, materials, chemistry, biology, and nanotechnology, micro/nanomotors are destined to evolve into powerful tools for fundamental neuroscience research and clinical neuromodulation.
