Structural modifications of toxyloxanthone C and macluraxanthone isolated from *Maclura cochinchinensis*: cytotoxicity, antibacterial activity, and *in silico* studies

 Chaiwat Linphosan,^a Waranya Klangswad,^b Jantana Yahuafai,^c Jinda Jandaruang,^d Trinop Promgool,^e Siripit Pitchuanom,^{ib} Jakkapat Paluka,^f Sophon Boonlue,^g Kitisak Poopasit,^b Kwanjai Kanokmedhakul^{ib} and Oue-artorn Limtragool^{ib}*^a

Toxyloxanthone C and macluraxanthone, isolated from the roots of *Maclura cochinchinensis*, have been reported to exhibit promising cytotoxic and antibacterial activities. Accordingly, thirteen xanthone derivatives were synthesized from these two parent xanthones by simple acylation, alkylation, sulfonylation, and bromination reactions. All derivatives were evaluated for their cytotoxicity against three cancer cell lines, HelaS3, A549, and HepG2, and their antibacterial activity against four Gram-positive bacterial strains, namely methicillin-resistant *Staphylococcus aureus*, *S. aureus*, *Bacillus subtilis*, and *Bacillus cereus*. 5,6-Diacetoxytoxyloxanthone C (**1a**) displayed cytotoxicity against three cancer cells with IC₅₀ values ranging from 12.20 to 22.61 μM. Additionally, **1a** demonstrated potent cytotoxicity against A549 cells with IC₅₀ = 12.20 μM, without showing cytotoxicity toward Vero cells. Moreover, 1,5,6-tripentanoyloxytoxyloxanthone C (**1b**) and 4-bromotoxyloxanthone C (**1f**) exhibited significant cytotoxicity against A549 cells with IC₅₀ values of 5.77 and 7.52 μM, respectively. In addition, **1a** and **1f** showed potent antibacterial activity against all bacteria tested with the same MIC value of 4 μg mL⁻¹, which was stronger than the parent xanthone **1**. Molecular docking studies revealed that **1a**, **1b**, and **1f** interacted with CDK2 through a competitive inhibition mechanism. Additionally, the binding conformations of **1a** and **1f** within the active sites of key enzymes involved in bacterial cell wall synthesis were similar to that of the tetracycline drug. The *in silico* physicochemical investigation indicated that **1a** and **1f** exhibited a favorable drug-likeness. Based on this finding, **1a** represents a promising lead candidate for further study as an anticancer and an antibacterial agent.

1 Introduction

Maclura cochinchinensis (Lour.) Corner is a shrub belonging to the Moraceae family and is widely distributed across various regions of Asia, including China, Japan, Korea, Taiwan, India,

Vietnam, Laos, and Thailand. Traditionally, the heartwood of this plant has been utilized in the treatment of chronic fever, diarrhea, and skin infections.^{1,2} Additionally, its leaves have been used for wound healing, while the roots have been employed in traditional medicine to treat bruising, boils, scabies, rheumatism, blood stasis, dysmenorrhea, and contusions.^{2,3} Xanthones and flavonoids, the major bioactive constituents isolated from *M. cochinchinensis*,²⁻⁷ have demonstrated a variety of biological activities, including antioxidant,¹ antibacterial,^{4,7} anticancer,^{1,3,4} and anti-inflammatory.^{2,6}

Several xanthone derivatives have been reported for structural modifications to enhance their biological activity. Three xanthones, α-mangostin, β-mangostin, and γ-mangostin, were partially modified under acidic conditions and subsequently evaluated for their antibacterial activities. Several of their analogues demonstrated improved pharmacokinetic properties. However, all modified derivatives showed weaker antibacterial activities against methicillin-resistant *Staphylococcus aureus* (MRSA), *Bacillus subtilis*, and *Pseudomonas aeruginosa*

compared to their parent compounds.⁸ Furthermore, α -mangostin was partially synthesized by cationic modification of the free 3-OH and 6-OH groups with amine moieties, followed by antibacterial evaluation. Some of its derivatives exhibited enhanced antibacterial potency against MRSA and *S. aureus*.⁹ Ananixanthone isolated from *Calophyllum teysmannii* stem bark, underwent structural modifications through acetylation, methylation, and benzylation at the 1-OH and 5-OH positions. The parent compound exhibited more potent cytotoxicity against SNU-1 (stomach cancer) and K562 (leukemia) cell lines. Among its derivatives, only 5-methoxyananixanthone exhibited superior cytotoxicity against LS174T (colon cancer) cells.¹⁰

Besides *M. cochinchinensis*, toxyloxanthone C (**1**) has been isolated from various plants such as *Cudrania*,^{11–15} *Cratogeomys*,¹⁶ and *Rheedia*¹⁷ species. It has been reported to exhibit antifungal,^{12,18} antibacterial,^{14,19} and cytotoxicity against HCT-116, SMMC-7721, SGC-7901, and BGC-823 cancer cell lines.^{13,18} Whereas, macluraxanthone (**2**) has been reported in the *Garcinia*,^{20–22} *Mesua*,²³ and *Calophyllum*²⁴ species. It has been shown cytotoxicity against several cancer cell lines such as HeLa, A549, PC-3, HT-29, WPMY-1, Hep G2, NCI-H23, and KB.^{20,21,24,25} Additionally, **2** exhibited *anti*-HIV,²⁰ antibacterial,⁴ and antimalarial.²⁶ From our previous report,⁴ xanthones **1** and **2** were isolated from *M. cochinchinensis*, they showed potent cytotoxicity toward three cancer cell lines, HeLaS3, A549, and HepG2 and also exhibited antibacterial activity against four Gram-positive bacteria MRSA, *S. aureus*, *B. subtilis*, and *Bacillus cereus*. Herein, further study of these bioactive xanthones is reported. The chemical structural modifications of parent xanthones **1** and **2** using simple organic reactions yielded thirteen xanthone derivatives. All compounds were evaluated for their cytotoxicity and antibacterial activity. Additionally, molecular docking simulations and drug-like property are also presented.

2 Result and discussion

2.1 Chemistry

From our previous reported,⁴ toxyloxanthone C (**1**) and macluraxanthone (**2**) were the main compounds isolated from the roots of *M. cochinchinensis*. Xanthone **1** exhibited cytotoxicity against the HeLaS3, A549, HepG2, and Vero cell lines with IC₅₀ values of 13.55 ± 1.11, 21.78 ± 4.89, 20.81 ± 2.57, and 8.52 ± 0.64 μ M, respectively. While xanthone **2** showed cytotoxicity against the HeLaS3, A549, HepG2, and Vero cell lines with IC₅₀ values of 1.59 ± 0.12, 6.46 ± 0.98, 5.26 ± 0.41, and 4.29 ± 0.60, respectively. In addition, **1** displayed antibacterial activity against MRSA, *S. aureus*, *B. subtilis*, and *B. cereus* with MIC values of 128 μ g mL⁻¹ for all strains, and **2** exhibited activities toward MRSA, *B. subtilis*, and *B. cereus* with MIC values of 16, 64, and 64 μ g mL⁻¹, respectively.⁴ To improve their bioactivities, structural modifications of **1** and **2** were performed. Thirteen xanthone derivatives were successfully synthesized using simple organic reactions, including acylation, alkylation, sulfonation, and bromination, as shown in Schemes 1 and 2.

According to literature,²⁷ acetyl substitution at 6-OH of α -mangostin exhibited significant antibacterial activity against

MRSA, which was better than the standard drug penicillin. Furthermore, the acetyl substitutions at 1-OH and 6-OH of α -mangostin, when combined with penicillin, exhibited greater antibacterial efficacy against MRSA compared to penicillin alone. Therefore, acylation reactions were applied to the parent xanthones **1** and **2** to investigate the antibacterial activity. Acetylation of **1** and **2** using acetic anhydride in pyridine afforded derivatives **1a** (41%) and **2a** (65%). The ¹H NMR data of **1a** showed two singlet signals of two methyl groups at δ_{H} 2.43 and 2.35, while the ¹³C NMR data of **1a** showed carbonyl signals at δ_{C} 167.7 and 167.4, corresponding to acetoxy groups. Similarly, the ¹H NMR data signals of **2a** at δ_{H} 2.39 and 2.34, together with its ¹³C NMR signals at δ_{C} 167.7 and 167.6, confirmed the presence of two acetoxy groups. Additionally, the ¹H NMR data of **1a** and **2a** exhibited intramolecular H-bonding signals at δ_{H} 12.84 and 13.40, respectively. Treatments of **1** and **2** with pentanoyl chloride in the presence of pyridine provided xanthone derivatives **1b** (11%) and **2b** (19%), respectively. Notably, the ¹H NMR spectra of **1b** and **2b** displayed no intramolecular H-bonding signal around δ_{H} 12.8 and 13.4, respectively. In addition, their ¹³C NMR spectra revealed three carbonyl signals at δ_{C} 172.6, 170.6, and 170.1 for **1b** and at δ_{C} 172.1, 170.6, and 170.5 for **2b**. In the acylation reactions, the use of a more electrophilic acid chloride resulted in acyl substitution at the 1-OH, 5-OH, and 6-OH positions.²⁷ Structural modifications were further carried out by treated **1** and **2** with methanesulfonyl chloride in pyridine, afforded mesylated derivatives **1c** (77%) and **2c** (88%). The ¹H NMR spectra of **1c** and **2c** showed singlet signals of two methyl groups at δ_{H} 3.49 and 3.38 for **1c**, as well as 3.43 and 3.33 for **2c**, corresponding to mesyl groups. According to a previous report,¹⁰ methylation of 5-OH group in ananixanthone resulted in enhanced cytotoxicity against the LS174T cell line compared to its parent compound. Therefore, alkylation reactions were carried out on xanthones **1** and **2** to further investigate their cytotoxic potential. Methylation of **1** using methyl iodide in the presence of sodium carbonate produced the dimethylated product **1d** (94%), whereas methylation of **2** yielded both a dimethylated product **2d** (45%) and a monomethylated product **2e** (14%). The ¹H NMR data of **1d** showed two methoxy signals at δ_{H} 4.00 and 3.99, whereas **2d** displayed two methoxy signals at δ_{H} 4.00 and 3.92. The ¹H NMR data of **2e** exhibited a singlet signal of a methoxy group at δ_{H} 4.01, while the HMBC spectrum revealed a correlation between these methoxy protons to C-5, confirming the substitution at the C-5 position. Ethylation of **1** using ethyl iodide in the presence of sodium carbonate provided diethylated product **1e** (86%), while **2** produced diethylated **2f** (70%) and monoethylated **2g** (27%) derivatives. In the alkylation reactions, **2** reacted with alkyl halide to yield both mono- and dialkylated products, which might due to the steric hindrance of the isoprenyl group at the C-4 position. Lastly, brominated xanthones was reported to demonstrate notable antibacterial activities against *S. aureus* and MRSA.²⁸ Consequently, the bromination reaction was applied to the parent xanthones **1** and **2** to analyze their antibacterial efficacy. Bromination of **1** using *N*-bromosuccinimide (NBS) in aqueous acetonitrile at room temperature afforded 4-bromoxanthone **1f** (36%). The ¹H

Scheme 1 Derivatives of toxyloxanthone C (1).

Scheme 2 Derivatives of macluraxanthone (2).

NMR data of **1f** showed the absence of the aromatic singlet signal around δ_{H} 6.4 corresponding to H-4, while the ^{13}C NMR data of **1f** showed a characteristic signal for the C-4 brominated carbon at δ_{C} 81.9, supporting the bromination position. In contrast, the reaction of **2** under the same bromination conditions did not yield any brominated product, due to the less nucleophilicity of the aromatic ring B.

2.2 Biological activity

Thirteen xanthone derivatives **1a–f** and **2a–g** were evaluated for their cytotoxicity against human cervical cancer cells (HelaS3), human lung cancer cells (A549), human liver cancer cells (HepG2), and African green monkey kidney cells (Vero), and the result is summarized in Table 1. The acetyl derivative **1a** displayed cytotoxicity against HelaS3, A549, and HepG2 cell lines, with IC_{50} values of 22.61 ± 2.02 , 12.20 ± 1.08 , and 21.10 ± 1.18 μM , respectively. Notably, **1a** exhibited twice cytotoxic potency against A549 cells compared to its parent xanthone **1**. Moreover, **1a** showed no cytotoxicity against normal cells ($\text{IC}_{50} > 100$ μM). Compound **1b** displayed strong toward A549 with IC_{50} values of 5.77 ± 2.14 μM , approximately fourfold higher than its parent **1**. However, **1b** also exhibits strong cytotoxicity to normal cells. In addition, **1b** demonstrated cytotoxicity against HepG2 with IC_{50} values of 17.15 ± 4.50 μM comparable to **1**. The acetyl derivative **2a** exhibited moderate cytotoxicity against three cancer cell lines with IC_{50} values in the range of 15.66 ± 1.17 to 25.55 ± 4.77 μM . The pentanoyl derivative **2b** showed weak cytotoxicity against HelaS3 ($\text{IC}_{50} = 55.31 \pm 2.18$ μM) and A549 ($\text{IC}_{50} = 41.84 \pm 1.91$ μM) cancer cells. This result indicated that the acyl derivatives of **2** decrease the cytotoxicity against the cancer cell lines tested. The mesylated derivatives, **1c** and **2c**, displayed weak cytotoxicity against HelaS3 cell line, with IC_{50} values of

65.33 ± 3.92 and 84.26 ± 7.86 μM , respectively. In contrast, the dimethylated products **1d** and **2d**, as well as the ethylated derivatives **2f** and **2g**, showed no cytotoxicity for all cancer cells tested. This suggested that the alkylation derivatives at the 5-OH and 6-OH positions of **1** and **2** reduce their cytotoxic potency. The bromoxanthone derivative **1f** demonstrated moderate cytotoxicity to HelaS3 and HepG2 cell lines, with IC_{50} values of 17.43 ± 1.75 and 19.42 ± 1.52 μM , respectively. In addition, **1f** exhibited strong cytotoxicity against A549 ($\text{IC}_{50} = 7.52 \pm 0.36$ μM), which is threefold higher than that of its parent **1**. However, **1f** showed cytotoxic toward normal cells. It was found that others derivative **2** in this study eliminated the cytotoxicity of all cancer cell lines tested. In conclusion, acylation and bromination of **1** enhance the cytotoxicity toward A549 cell line, but only acetyl **1a** has the potential to be developed as an anticancer drug targeting A549 cells, as it has anticancer activity without causing toxicity to normal cells ($\text{IC}_{50} > 100$ μM).

All xanthone derivatives **1a–f** and **2a–g** were further evaluated for antibacterial activity against four Gram-positive bacteria, including MRSA, *S. aureus*, *B. subtilis*, and *B. cereus*, using the microdilution method (Table 2). Compounds **1a** and **1f** exhibited significant antibacterial efficacy against all bacterial strains with the same MIC value at 4 $\mu\text{g mL}^{-1}$, representing 32-fold improvement in potency compared to their parent **1**. Similarly, **1b** also showed notable activity with MIC values ranging from 8 to 16 $\mu\text{g mL}^{-1}$, indicated their increasing potency activity compared to its parent **1**. This suggested that acylation and bromination of **1** enhanced antibacterial activity. Compounds **1c**, **1d**, and **1e** showed no antibacterial activity against all bacterial strains. It should be noted that sulfonylation and alkylation at the 5-OH and 6-OH positions decreased the antibacterial activity. In case of derivatives of **2**, only the acetyl derivative **2a** exhibited antibacterial activity against all tested

bacteria with MIC values ranging from 8 to 32 $\mu\text{g mL}^{-1}$, which showed more effective than its parent xanthone. While the other derivatives **2b–g** exhibited no antibacterial activity against all tested bacteria. This revealed that the sulfonylation and alkylation of **2** reduced their antibacterial activity.

2.3 Molecular docking simulation

Molecular docking simulations were performed using the AutoDock program to elucidate the binding interactions of the active xanthenes (**1**, **1a**, **1b**, and **1f**) with cyclin-dependent kinase 2 (CDK2). As a key regulator of the cell cycle, CDK2 is frequently overexpressed in various cancers, resulting in dysregulated proliferation and tumor progression.²⁹ Therefore, the inhibition of CDK2 could be a pharmacological strategy for cancer treatment.^{29–32} The crystal structure of CDK2 in complex with the inhibitor RC-3-89 was validated by a redocking experiment, and the results are summarized in Fig. 1 and Table 3. The ligand RC-3-89 occupied the ATP binding site of CDK2, interacting with key amino acid residues in the hinge region (Glu81, Phe82, and Leu83), the front specificity pocket (Asp86 and Lys89), the DFG motif (Asp145), and the hydrophobic pocket (Ile10, Val18, Ala31, and Leu134).²⁹ Consistently, compounds **1**, **1a**, **1b**, and **1f** were also accommodated within the ATP binding site of CDK2 in the hinge region, suggesting a competitive inhibition mechanism (Fig. 2a).^{32,33} The xanthone core structure of all docking compounds formed hydrophobic interactions in the hydrophobic pocket of CDK2, as shown in Fig. 1. The docking analysis of **1** revealed the formation of three hydrogen bonds in the hinge region, including the interactions of 5-OH with Leu83 and Glu81, as well as 6-OH with Glu81. Compound **1** formed hydrogen bond with Asp86 and pi-alkyl

with Lys89 in the front specificity pocket. Compound **1a** interacted with CDK2 through hydrogen bonding with Leu83, Asp86, and Asp145, consistent with the binding interaction observed for the reference ligand RC-3-89, as shown in Fig. 1 and 2b. Compound **1b** demonstrated the lowest binding energy among the xanthone derivatives, with a binding energy of $-9.78 \text{ kcal mol}^{-1}$. The two carbonyl moieties of pentanoyl groups formed hydrogen bonds with Asp86 and Lys89 amino acids. Additionally, the side chains of pentanoyl moieties created hydrophobic interactions in the hydrophobic pocket with Ile10, Ala31, and Leu134 as well as with the gatekeeper residue Phe80. The results suggested that the pentanoyl substitutions may enhance the stability of the compound within the hydrophobic pocket of the ATP binding site. Docking analysis of **1f** demonstrated hydrogen bonding interactions of 1-OH, 5-OH, and 6-OH with Gln131, Leu83, and His84, respectively. Additionally, the bromine atom formed hydrophobic interactions with Ala31, Phe82, and Leu134 residues, which may play a crucial role in stabilizing the protein-ligand interaction.

Molecular docking studies were investigated to support the *in vitro* antibacterial activity toward MRSA, *B. subtilis*, and *B. cereus*, using the penicillin-binding protein 2a (PBP2a) from MRSA,³⁴ the *B. subtilis* TagU,^{35,36} and the secondary cell wall polysaccharides (SCWP) *O*-acetyltransferase of *B. cereus*³⁷ as the protein templates. The PBP2a is crucial transpeptidase enzyme for the cell wall synthesis and β -lactam antibiotic resistance in MRSA.^{34,38} In contrast, the *B. subtilis* LytR-CpsA-Psr (LCP) enzyme play a crucial role in cell wall assembly and maintenance. This enzyme is responsible for transferring wall teichoic acids and capsular polysaccharides onto the peptidoglycan of Gram-positive bacteria.³⁵ SCWP *O*-acetyltransferase is an essential enzyme for the stable binding of S-layer proteins to the

Fig. 1 The binding interactions of RC-3-89, **1**, **1a**, **1b**, and **1f** with CDK2.

Table 3 Summary of the binding interactions and energies of active xanthone with CDK2, PBP2a of MRSA, and SCWP *O*-acetyltransferase of *B. cereus*

Compound	Binding energy (kcal mol ⁻¹)	Protein-ligand interactions

**Fig. 2** (a) Docking poses of **1** (green), **1a** (purple), **1b** (yellow), and **1f** (pink) onto the active site of CDK2 and (b) superimposed conformation of co-crystallized ligand (green) and **1a** (purple) onto the active site of CDK2.

bacterial cell wall, resulting in the enhanced structural integrity of cell wall.³⁷ Therefore, the molecular docking of these key enzymes involved in cell wall synthesis of bacterial pathogens was performed to elucidate their potential for treating bacterial infections. Tetracycline was investigated as a control for all proteins and the results are summarized in Table 3. The active site of the PBP2a of MRSA consists of the amino acid residues Ser403, Lys406, Tyr446, Ser462, Asn464, Ser598, Gly599, Thr600, and Met641.³⁴ Tetracycline exhibited the lowest binding energy of -8.35 kcal mol⁻¹ and formed hydrogen bonds with key amino acid residues Ser403, Tyr446, Ser462, Asn464, and Ser598 within the PBP2a active site of the transpeptidase domain (Fig. 3). Compounds **1a** and **1f** demonstrated the binding energy

of -8.02 and -7.29 kcal mol⁻¹, respectively, within the PBP2a active site. Compound **1a** established hydrogen bonds with Ser403, Asn464, and Met641 and formed pi-pi stacking with Tyr446. Significantly, the carbonyl of acetyl groups formed hydrogen bonds with Glu602 and Asn464, indicating that the acetyl groups may play an important role in antibacterial against MRSA. Compound **1f** established hydrogen bonds with Ser403, Ser462, and Ser598. Moreover, the superimposed conformation of **1f** in the PBP2a active site was similar to those of tetracycline, as shown in Fig. 6a. According to the docking results of *B. subtilis*, the amino acids Asp75, Arg83, Asp85, Arg106, Asp107, Lys120, Phe156, Arg198, Arg200, Asp207, and Arg210 are considered as the active site of *B. subtilis* LCP

Fig. 3 The binding interactions of tetracycline, **1a**, and **1f** with the PBP2a of MRSA.

Fig. 4 The binding interactions of tetracycline, **1a**, and **1f** with *B. subtilis* LCP enzyme.

enzyme.³⁵ Tetracycline showed a binding energy of -5.86 kcal mol⁻¹ and formed hydrogen bonds with Asp75, Asp207, Arg210, and Gln214 (Fig. 4). Compound **1a** demonstrated the lowest binding energy of -7.55 kcal mol⁻¹. Its xanثone core structure formed electrostatic interactions with key amino residues Asp75, Asp85, and Arg210. The carbonyl group at C-5 formed three hydrogen bonds with Thr197, Arg210, and Gln214 amino acids. The docking poses of **1a** exhibited similar orientation to that of tetracycline in the active site (Fig. 6b). Compound **1f** established a hydrogen bond with Gln211, while its bromine atom interacted with Pro105 and Phe208 through hydrophobic interactions. For the SCWP *O*-acetyltransferase molecular docking result of *B. cereus*, the amino acid residues Lys186, His201, His202, Ser337, Ser354, Arg359, and Ser364 are considered as the active site of SCWP *O*-acetyltransferase of *B.*

cereus.³⁷ The binding energy of tetracycline was calculated to be -5.75 kcal mol⁻¹ (Table 3). Docking analysis revealed that tetracycline formed hydrogen bonds with Lys103, Asn104, Asn251, and Ser385. Additionally, it exhibited a pi-cation interaction with Arg359 and pi-alkyl interactions with His201 and His202 (Fig. 5). Compound **1a** displayed a hydrogen bond and a pi cation interaction with the key amino acids Arg359 and His201, respectively. Furthermore, the acetyl groups of **1a** established hydrogen bonds with the Lys103 and Asn104 residues, indicating that the acetyl groups could improve antibacterial toward *B. cereus*. Compound **1f** formed three hydrogen bonds with Lys103, Asn251, and Ser385 and pi-cation interactions with the key amino acids His201 and Arg359. The bromine atom established a halogen bond with Asp92, suggesting its role in stabilizing the protein-ligand interaction. Moreover, the

Fig. 5 The binding interactions of tetracycline, **1a**, and **1f** with SCWP *O*-acetyltransferase of *B. cereus*.

Fig. 6 The superimposed conformations of (a) tetracycline (purple) and **1f** (green) with the PBP2a of MRSA, (b) tetracycline (purple) and **1a** (yellow) with *B. subtilis* LCP enzyme, and (c) tetracycline (purple), **1a** (yellow), and **1f** (green) with SCWP *O*-acetyltransferase of *B. cereus*.

binding energy of **1a** and **1f** was lower than that of tetracycline. Structural superimpositions of **1a**, **1f**, and tetracycline further confirmed their similar binding interaction within the active site (Fig. 6c).

2.4 Physicochemical properties

Lipinski's and Veber's rules were used to evaluate the drug-likeness of all compounds, and the results are summarized in Table 4. Lipinski's rule considers many criteria, including molecular weight ($MW \leq 500$), hydrogen bond acceptors ($HBA \leq 10$), hydrogen bond donors ($HBD \leq 5$), and $\log P$ (lipophilicity index < 5).³⁹ A compound that violates more than one of these criteria is less likely to be an orally active drug. All compounds, except for **1b** and **2b**, meet these criteria, suggesting their potential for good oral bioavailability. These indicated that the structural modification of both parent compounds with pentanoyl chloride tends to compromise their drug-like properties. While Veber's rule considers the number of rotatable bonds ($NORTB \leq 10$) and topological polar surface area ($TPSA \leq 140$).⁴⁰ Most compounds, with the exception of **1b**, **2b**, **1c**, and **2c**, comply with both criteria, supporting the favorable oral absorption. The results of Lipinski's and Veber's rules indicated that compounds **1a** and **1f** could be developed to be the orally active drug.

3 Experimental

3.1 General experimental procedures

Melting points were determined on a SANYO Gallenkamp (Leicester, UK) melting point apparatus and are uncorrected. IR spectra were taken on a PerkinElmer Spectrum One spectrophotometer (Agilent Technologies, U.S.A.). NMR spectra were recorded in $CDCl_3$ and CD_3OD on a Bucker Ascend 400 MHz (Bruker, Germany). Mass spectra were performed on an Agilent 1260 Infinity series high-performance liquid chromatography system (Agilent, Waldbronn, Germany), coupled with a 6540 ultra-high-definition accurate mass spectrometer (Agilent Technologies, Singapore). Column chromatography was carried out on SiliCycle silica gel (40–63 μm , SiliCycle, Inc., Canada), TLC was performed with precoated Merck silica gel 60 PF254 on an aluminum (Merck, Darmstadt, Germany).

3.2 Plant material

Roots of *Maclura cochinchinensis* were collected from Pattani province, Thailand.⁴ The specimens were identified by Prof. Pranom Chantaranothai, Department of Biology, Khon Kaen University, Thailand, where a voucher specimen (SK17) was deposited.

Table 4 Physicochemical properties of modified and parent compounds by *in silico* analysis

3.3 Preparation of xanthone derivatives

3.3.1 Isolation of toxylloxanthone C (1) and macluraxanthone (2). The starting xanthone, macluraxanthone (2), was obtained from the crude hexane and EtOAc extracts of the root of *M. cochinchinensis*. Meanwhile, toxylloxanthone C (1) was recrystallized from the solid of subfraction E7.1 using MeOH as a solvent, following the procedure described in a previous publication.⁴

Toxylloxanthone C (1); yellow solid; $[\alpha]_D^{24} +17.7$ (*c* 0.36, acetone);⁴¹ ¹H NMR (400 MHz, (CH₃)₂CO) δ 13.45 (1H s, 1-OH), 7.60 (1H, d, *J* = 8.4 Hz, H-8), 6.96 (1H, d, *J* = 8.4 Hz, H-7), 6.30 (1H, s, H-4), 4.50 (1H, q, *J* = 6.8 Hz, H-12), 1.46 (s, 3H, H-14), 1.36 (3H, d, *J* = 6.4 Hz, H-13), 1.22 (3H, s, H-15); ¹³C NMR (100 MHz, (CH₃)₂CO) δ 181.2 (C-9), 166.2 (C-1), 159.1 (C-3), 158.2 (C-4a), 151.6 (C-6), 146.5 (C-10a), 132.7 (C-5), 117.0 (C-8), 116.9 (C-8a), 114.2 (C-2), 113.3 (C-7), 103.6 (C-9a), 91.3 (C-12), 89.6 (C-4), 43.6 (C-11), 25.0 (C-14), 20.5 (C-15), 14.2 (C-13); HRESI-MS *m/z* 329.1025 [M + H]⁺ (Calc. for 329.1025, C₁₈H₁₇O₆).

Macluraxanthone (2); yellow crystals; ¹H NMR (400 MHz, CD₃OD) δ 7.56 (1H, d, *J* = 8.8 Hz, H-8), 6.88 (1H, d, *J* = 8.4 Hz, H-7), 6.69 (1H, d, *J* = 10.0 Hz, H-11), 6.44 (1H, dd, *J* = 17.6, 10.4 Hz, H-19), 5.64 (1H, d, *J* = 10.0 Hz, H-12), 4.99 (1H, dd, *J* = 17.6, 1.2 Hz, H-20a), 4.84 (1H, dd, *J* = 10.4, 1.2 Hz, H-20b), 1.73 (6H, s, H-17, H-18), 1.47 (6H, s, H-14, H-15); ¹³C NMR (100 MHz, CD₃OD) δ 182.5 (C-9), 160.1 (C-1), 157.3 (C-3), 156.6 (C-4a), 152.8 (C-19), 152.7 (C-6), 147.5 (C-10a), 134.2 (C-5), 128.4 (C-12), 117.1 (C-11), 116.8 (C-8), 114.9 (C-8a), 114.6 (C-7), 113.7 (C-4), 107.7 (C-20), 106.1 (C-2), 103.9 (C-9a), 79.3 (C-13), 42.2 (C-16), 30.2 (C-17, C-18), 28.1 (C-14, C-15); HRESI-MS: *m/z* 395.1496 [M + H]⁺ (Calc. for C₂₃H₂₃O₆ 395.1495).

3.3.2 General procedure to prepare 1a–c and 2a–c.^{42,43} Toxylloxanthone C (1) (24.3 mg, 0.074 mmol) or macluraxanthone (2) (27.9 mg, 0.071 mmol) was dissolved in pyridine (2 mL), followed by the dropwise addition of an excess of acetic anhydride (Ac₂O) at 0 °C. The reaction mixture was stirred at room temperature for 2 hours. The reaction mixture was poured into

cold water (20 mL) and extracted with EtOAc (2 × 20 mL). The organic layer was combined, washed with water and brine, dried over anhydrous Na₂SO₄, filtered, and evaporated under reduced pressure to obtain a crude solid. Recrystallization of a crude solid from hexane yielded **1a** (12.8 mg, 41%) or **2a** (22 mg, 65%).

The reactions of **1** or **2** with pentanoyl chloride or methanesulfonyl chloride were performed following the same procedure described above, affording **1b** (10.2 mg, 11%), **1c** (27.3 mg, 77%), **2b** (19.9 mg, 19%), and **2c** (34.3 mg, 88%), respectively.

3.3.2.1 General procedure to prepare 1d–e and 2d–g.⁴² To a solution of toxylloxanthone C (1) (30.0 mg, 0.089 mmol) or macluraxanthone (2) (59.2 mg, 0.15 mmol) in dry acetone (2 mL), anhydrous sodium carbonate (160 mg), and methyl iodide (0.12 mL) were added. The reaction mixture was refluxed overnight. The reaction was quenched by the addition of cold water and extracted with EtOAc (2 × 20 mL). The organic combined layer was washed with water, brine, and dried over anhydrous Na₂SO₄. Evaporation of the solvent gave a crude oil. The crude product was purified by silica gel column chromatography using 20% EtOAc/hexane as an eluent, yielding **1d** (30.2 mg, 94%) or **2d** (28.6 mg, 45%) and **2e** (8.6 mg, 14%).

The reaction of **1** (49.0 mg, 0.149 mmol) or **2** with ethyl iodide (EtI) (59.1 mg, 0.149 mmol) was performed in the same procedure as described above, yielding **1e** (42.3 mg, 86%), or **2f** (41.7 mg, 70%) and **2g** (13.4 mg, 27%).

3.3.3 Bromination using N-bromosuccinimide (NBS).⁴³ Toxylloxanthone C (1) (30.8 mg, 0.094 mmol) was dissolved in EtOAc (2 mL), and a solution of NBS (0.155 mmol) in MeCN:H₂O (1:1, 2 mL) was added dropwise at 0 °C. The reaction mixture was stirred at 0 °C for 1 hour, followed by stirring at room temperature for 1 hour. The reaction mixture was poured into cold water (20 mL) and extracted with EtOAc (2 × 20 mL). The organic layer was combined, washed with water and brine, dried over anhydrous Na₂SO₄, and concentrated under reduced pressure to afford a crude solid. Recrystallization from hexane

yielded **1f** (24.2 mg, 36%). Bromination of macluraxanthone (**2**) (37.3 mg, 0.094 mmol) using the same procedure resulted in no product formation.

3.4 Spectroscopic data

5,6-Diacetoxyxyloxyloxanthone C (**1a**); yellow solid; mp 164.1–165.3 °C; IR ν_{\max} (cm⁻¹); 2965, 2915, 1775, 1648, 1579, 1428, 1370, 1260; ¹H NMR (400 MHz, CDCl₃) δ 12.84 (1H, s, 1-OH), 8.14 (1H, d, *J* = 8.8, 0.8 Hz, H-8), 7.20 (1H, d, *J* = 8.8, 0.8 Hz, H-7), 6.29 (1H, s, *J* = 0.8 Hz, H-4), 4.52 (1H, q, *J* = 6.8 Hz, H-12), 2.43 (3H, s, H-2''), 2.35 (3H, s, H-2'), 1.50 (3H, s, H-14), 1.39 (3H, d, *J* = 6.8 Hz, H-13), 1.26 (3H, s, H-15); ¹³C NMR (100 MHz, CDCl₃) δ 179.9 (C-9), 167.7 (C-1''), 167.4 (C-1'), 166.5 (C-1), 158.8 (C-3), 157.6 (C-4a), 149.2 (C-6), 147.4 (C-10a), 130.1 (C-5), 123.5 (C-8), 119.6 (C-8a), 118.6 (C-2), 117.6 (C-7), 104.2 (C-9a), 91.4 (C-12), 90.1 (C-4), 43.4 (C-11), 25.3 (C-2''), 20.8 (C-2'), 20.7 (C-14), 20.4 (C-15), 14.5 (C-13); HRESI-MS *m/z* 413.1245 [M + H]⁺ (Calc. for 413.1236, C₂₂H₂₁O₈).

1,5,6-Tripentanoyloxyxyloxyloxanthone C (**1b**); white solid; mp 85.2–87.9 °C; IR ν_{\max} (cm⁻¹); 2958, 2935, 2873, 1765, 1658, 1456, 1418, 1257; ¹H NMR (400 MHz, CDCl₃) δ 8.13 (1H, d, *J* = 8.8 Hz, H-8), 7.15 (1H, d, *J* = 8.8 Hz, H-7), 6.47 (1H, s, H-4), 4.59 (1H, q, *J* = 6.4 Hz, H-12), 2.77 (2H, t, *J* = 7.6 Hz, H-2''), 2.67 (2H, t, *J* = 7.6 Hz, H-2'), 2.59 (2H, t, *J* = 7.6 Hz, H-2'), 1.97–1.67 (6H, m, H-3'', H-3' and H-3'), 1.54 (3H, s, H-14), 1.48 (6H, m, H-4'', H-4' and H-4'), 1.43 (3H, d, *J* = 6.4 Hz, H-13), 1.43 (3H, s, H-15), 1.10–0.92 (9H, m, H-5'', H-5', H-5'); ¹³C NMR (100 MHz, CDCl₃) δ 173.8 (C-9), 172.6 (C-12), 170.6 (C-1''), 170.1 (C-1'), 164.1 (C-1), 154.0 (C-3), 152.2 (C-4a), 148.5 (C-6), 147.3 (C-10a), 130.8 (C-5), 124.4 (C-8), 121.2 (C-8a), 120.1 (C-2), 118.7 (C-7), 109.5 (C-9a), 103.6 (C-12), 91.4 (C-4), 44.5 (C-11), 34.2 (C-2''), 33.9 (C-2'), 33.6 (C-2'), 27.0 (C-3''), 26.9 (C-3''), 26.7 (C-3'), 25.8 (C-14), 22.42 (C-4''), 22.38 (C-4''), 22.38 (C-4'), 21.3 (C-15), 14.4 (C-13), 14.0 (C-5''), 13.9 (C-5''), 13.8 (C-5'); HRESI-MS *m/z* 581.2718 [M + H]⁺ (Calc. for 581.2751, C₃₃H₄₁O₉).

5,6-Dimesyloxyxyloxyloxanthone C (**1c**); yellow solid; mp 191.1–192.3 °C; IR ν_{\max} (cm⁻¹); 3020, 2940, 1648, 1597, 1448, 1355, 1274; ¹H NMR (400 MHz, CDCl₃) δ 12.65 (1H, s, 1-OH), 8.20 (1H, d, *J* = 8.8 Hz, 1H, H-8), 7.48 (1H, d, *J* = 8.8 Hz, H-7), 6.30 (1H, s, H-4), 4.55 (1H, q, *J* = 6.8 Hz, H-12), 3.49 (3H, s, 6-OSO₂CH₃), 3.38 (3H, s, 5-OSO₂CH₃), 1.50 (3H, s, H-14), 1.40 (d, *J* = 6.8 Hz, 3H, H-13), 1.26 (s, 3H, H-15); ¹³C NMR (400 MHz, CDCl₃) δ 180.0 (C-9), 166.9 (C-1), 158.9 (C-3), 157.3 (C-4a), 149.5 (C-6), 146.6 (C-10a), 130.1 (C-5), 125.1 (C-8), 120.6 (C-8a), 118.6 (C-2), 118.3 (C-7), 104.0 (C-9a), 91.7 (C-12), 89.9 (C-4), 43.5 (C-11), 40.3 (6-OSO₂CH₃), 39.5 (5-OSO₂CH₃), 25.3 (C-14), 20.7 (C-15), 14.5 (C-13); HRESI-MS *m/z* 485.0579 [M + H]⁺ (Calc. for 485.0576, C₂₀H₂₁O₁₀S₂).

3.5 Cytotoxicity and cell proliferation assays

All types of cancer and non-tumorigenic cells were purchased from ATCC. Cytotoxicity assays against human cervical carcinoma (HelaS3; ATCC CCL2-2), human hepatocellular carcinoma (HepG2; ATCC HB-8065), human lung carcinoma (A549; ATCC CCL-185), and African green monkey kidney (Vero; ATCC CCL-81) cell lines were performed by terminal deoxynucleotidyl transferase (TdT) dUTP Nick-End Labeling (TUNEL) assay.⁴⁴ Cells proliferation was performed using the MTT colorimetric assay,⁴⁴ as in our previous publication.⁴

3.6 Antibacterial assay

Four bacterial cultures *Bacillus cereus* ATCC 11778, *Bacillus subtilis* ATCC 6633, *Staphylococcus aureus* ATCC 25923, and Methicillin resistant *Staphylococcus aureus* (MRSA) were employed as the test organisms. Minimum inhibitory concentration (MIC) values were determined using the dilution method, as described in the M07-A9,⁴⁵ as described in our previous paper.^{4,46}

3.7 Molecular docking simulation

All the calculations were performed on Intel® Core™ i7-12700F CPU 2.11 GHz with 32 GB DDR4 RAM. The crystallographic structures of cyclin-dependent kinase 2 (CDK2) in complex with the inhibitor RC-3-89 (PDB code: 4GCJ), methicillin acylpenicillin binding protein 2a from methicillin resistant *Staphylococcus aureus* (PDB code: 1MWU), and *Bacillus cereus* PatB1 (PDB code: 5V8E) were obtained from the Protein Data Bank. The existing ligands and water molecules were removed from the crystal structure. Molecular docking studies were performed using the AutoDock 4.2.6 program.⁴⁷ The 3D structures of compounds **1**, **1a**, **1b**, and **1f** were minimized at the B3LYP/6-

31G(d) levels using the Gaussian 03 program. All hydrogens were added and Gasteiger charges were assigned by using AutoDockTools.⁴⁷ A grid box of 40 × 40 × 40 points was centered at the coordinates of the RC-3-89 inhibitor ($x = -51.563$, $y = 98.287$, $z = -62.755$) to define the binding site of the CDK2 protein. Similarly, the grid box was generated at the center of the coordinate's ligand with dimensions of 40 × 40 × 40 points, centered at $x = 28.221$, $y = 28.839$, and $z = 87.515$ for PBP2a from MRSA, and centered at $x = -67.474$, $y = -1.104$, and $z = -15.158$ for *Bacillus cereus* PatB1. For *B. subtilis* TagU, a grid box was generated in the absence of a co-crystallized ligand to cover all active site residues³⁵ with dimensions of 70 × 70 × 70 points, centered at $x = 8.698$, $y = 24.542$, and $z = 24.418$. All grid boxes were constructed with a grid spacing of 0.375 Å. The optimized ligands were docked onto protein templates using the Lamarckian genetic algorithm. The docking protocol was set to default, with 150 independent docking runs. The protein templates of CDK2, PBP2a from MRSA, and SCWP O-acetyltransferase of *B. cereus* exhibited the best results of redocking experiments with the RMSD of 0.68, 1.67, and 1.42 Å, respectively (Table S1). Finally, the docking results were then analyzed to identify the best cluster of each compound with the lowest free binding energy. Protein–ligand interactions were visualized by using the Discovery Studio 2021 Client program (Accelrys, Inc., San Diego, CA, USA).

3.8 *In silico* physicochemical properties

The physicochemical properties of all compounds were evaluated to assess their potential as drug candidates using the SwissADME⁴⁸ web server. Drug-likeness was verified using the Lipinski's and Veber's rules.

4 Conclusions

Two main compounds, toxylloxanthone C (**1**) and macluraxanthone (**2**) from *M. cochinchinensis* roots, have been structurally modified through simple organic reactions including acylation, alkylation, sulfonylation, and bromination yielding thirteen derivatives **1a–f** and **2a–g**. All compounds were evaluated for their cytotoxic and antibacterial activities. Compounds **1a**, **1b**, and **1f** exhibited greater cytotoxic potency against A549 cells compared to their parent compound. Molecular docking studies revealed that **1a**, **1b**, and **1f** bound to CDK2 through hydrogen bonding and hydrophobic interactions with key amino acid residues. Furthermore, **1a** and **1b** demonstrated lower binding energies than **1**. Notably, **1a** exhibited potential as a lead anticancer candidate for further development due to its strong cytotoxicity with minimal toxicity toward normal cells. Additionally, **1a**, **1b**, **1f**, and **2a** displayed stronger antibacterial activity against four bacterial strains than their parent compounds. The docking results indicated that **1a** and **1f** interacted with key amino acids in the PBP2a active site of MRSA. In addition, the binding conformation of **1a** in the active site of LCP enzyme from *B. subtilis* aligned with that of tetracycline. While **1a**, **1f**, and tetracycline exhibited similar binding orientations with the key amino

acids within the active site of *B. cereus*. The physicochemical properties of **1a** and **1f** satisfied Lipinski's and Veber's rules, supporting their potential as drug-like candidates. Most derivatives of **2** exhibited reduced anticancer and antibacterial activities compared to the parent xanthone. This decrease in activity is likely due to steric hindrance between the prenyl group at the C-4 position and the additional substituents introduced in the derivatives, a structural effect consistent with previous reports on modified prenylated xanthenes.^{10,27} Overall, **1a** and **1f** exhibited significant dual bioactivities, showing cytotoxicity against A549 cells and antibacterial activity against four bacterial cultures; however, **1f** also displayed cytotoxicity toward Vero cells. Therefore, 5,6-diacetoxytoxylloxanthone C (**1a**) is interesting candidate for further study as anticancer and antibacterial agents.

Author contributions

C. Linphosan performed the experiments, analyzed the data, evaluated antibacterial activity, and drafted the initial manuscript. W. Klangawad isolated parent compounds. J. Yahuafai performed cytotoxicity assay. J. Jandaruang and T. Promgool evaluated antibacterial activity. S. Pitchuanom supervised the molecular docking studies. J. Paluka and S. Boonlue provided antibacterial testing facilities. K. Poopasit carried out the NMR experiment. K. Kanokmedhakul to consultant and manuscript editing. O. Limtragool, the principal investigator, designed the experiments, analyzed the data, conducted *in silico* studies, and prepared the manuscript.

Conflicts of interest

The authors declare no conflict of interest.

Data availability

The datasets supporting this article have been uploaded as part of the SI. See DOI: <https://doi.org/10.1039/d5ra05758b>.

Acknowledgements

This research project was financially supported by Thailand Science Research and Innovation (TSRI). Linphosan C. thanks the Center of Excellence for Innovation in Chemistry (PERCH-CIC). We acknowledge the Office of the Permanent Secretary, Ministry of Higher Education, Science, Research and Innovation (OP S MHESI, Grant No. RGNS 64–140) for partial support. We thank Prof. Chavi Yenjai for providing chemical support for this research.
