## Polymer Chemistry

Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about *Accepted Manuscripts* in the **Information for Authors**.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard <u>Terms & Conditions</u> and the <u>Ethical guidelines</u> still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

## COMMUNICATION

## **Reactive Imidazole Intermediates: Simplified Synthetic Approach to Functional Aliphatic Cyclic Carbonates**

Johan V. Olsson,<sup>a</sup> Daniel Hult,<sup>a</sup> Yanling Cai,<sup>a</sup> Sandra García-Galliardo<sup>a</sup> and Michael Malkoch\*,<sup>a</sup>

Received (in XXX, XXX) Xth XXXXXXXX 20XX, Accepted Xth XXXXXXXX 20XX 5 DOI: 10.1039/b000000x

Reactive imidazole intermediates based on  $AB_2$  and  $A_3$ monomers i.e. bis(methylol) propionic acid (bis-MPA) and trimethylolpropane (TMP) have successfully been synthesized and isolated in 100 grams scale via a facile synthetic protocol

- <sup>10</sup> using 1,1'-carbonyldiimidazole (CDI) as a key reagent. The robustness of the imidazole intermediates as bench stable precursors enabled the synthesis of a library of functional cyclic carbonates bearing relevant functionalities including hydrophilic PEGs, bioactive cholesterol and clickable groups.
- <sup>15</sup> A number of functional polycarbonates were obtained by ring-opening polymerization, and their relevance for biomedical applications was highlighted by their low cytotoxicity on human dermal fibroblasts (hDF).

With the apparent demand for functional polymers needed to <sup>20</sup> fulfil the criteria set by a modern society, scientists, only limited by their imagination, are constantly proposing novel architectures. Polycarbonates (PCs), particularly functional aliphatic polycarbonates (FAPCs) with pendant reactive groups along the main chain have recently received significant attention

- <sup>25</sup> due to their envisioned use in biomedical applications.<sup>1</sup> An attractive feature of PCs, in comparison to polyesters, is their biodegradation profile that proceed without concomitant acid formation.<sup>2</sup> In contrast, biodegradation of polyesters may lead to high local concentrations of acid *in-vivo*<sup>3</sup> which could impact
- <sup>30</sup> acid-labile drug-delivery systems. The utility of FAPCs ranges from promising candidates as artificial biomaterials to passive drug delivery systems.<sup>4</sup> Despite their great potential, the availability of FAPCs is limited by tedious synthetic schemes including multiple reaction steps.<sup>5</sup>
- A similar and relevant comparison of synthetic challenges can be correlated to functional and monodisperse dendrimers. More specifically, the family of aliphatic polyester based on the simple  $AB_2$  monomer 2,2-bis(methylol) propionic acid (bis-MPA). From the first synthetic report of a relevantly simple dendrimer,
- <sup>40</sup> isolated in mg scales, to large scale simplified approaches accomplished in one day,<sup>6</sup> the bis-MPA monomer has passed a cascade of synthetic refinements, including click chemistry concepts.<sup>7</sup> Today, a myriad of structurally different dendritic architectures based on bis-MPA is accessible and exploited in a
- <sup>45</sup> broad range of application-driven research.<sup>7a</sup> With excellent biocompatible, nontoxic and biodegradable properties, their

scaffolding evaluation is heavily focused towards the field of biomedicine, especially as promising drug delivery systems.<sup>8</sup> In the context of PCs, Fréchet and coworkers described a novel 50 synthetic strategy to end-heterofunctional bis-MPA dendrimers utilizing covalently attached cyclic carbonate bis-MPA monomer. 5-methyl-5-carboxyl-1,3-dioxane-2-one (MCC) at the periphery of the framework.9 This was accomplished by successful carbonvlation of the pendant 1,3-diols groups of the MCC. 55 Subsequent amine-induced ring opening of the carbonatefunctional dendrimer resulted in the desired peripheral heterofunctionality.<sup>9</sup> Notably, functional cyclic carbonates, including MCC, are orthogonal in nature and can undergo selective ring opening polymerization (ROP) resulting in FAPCs. 60 Due to their attractive biomedical properties, cationic amphiphilic nanoparticles based on FAPCs were recently found to exhibit excellent antimicrobial effects on bacteria by microbial wall/membrane disruption mechanisms, thus hindering the

- growth of bacteria such as methicillin-resistant Staphylococcus 65 aureus (MRSA).<sup>10</sup> As FAPCs continue to migrate into various research fields, a critical challenge to overcome is improving available synthetic pathways. In this context, Hedrick and coworkers<sup>11</sup> reported on the synthesis of bench-stable pentafluorophenyl 1,1,1substituted bis-MPA and 70 tris(hydroxylmethyl)ethane (TME). Their findings utilized a tandem carbonylation/pendant-group activation mechanism, thus avoiding tedious protection group chemistry. This strategy is today recognized as the most versatile approach to fast and efficient generation of a variety of functional carbonates. 75 Unfortunately, the fluorinated reagent is still rather expensive, resulting in functional carbonates mostly limited to gram scales. Therefore, further simplification of the synthetic methodology is inevitable to further facilitate the availability of these significant and functional building-blocks on larger synthetic scales.
- <sup>80</sup> We herein present a robust and economical synthetic protocol for synthesis of functional cyclic carbonates utilizing 1,1'carbonyldiimidazole (CDI) as reagent. Incentives for using CDI include its ready availability, low price and safety for handling and storage. Previously, CDI has been widely used as reagent for <sup>85</sup> formation of urethane, urea, ester and amide-linkages.<sup>12</sup> It has also been exploited for synthesis of peptides,<sup>13,14</sup> dendritic polymers,<sup>15</sup> cellulose surfaces,<sup>16</sup> and even for 5- and 6membered cyclic carbonates.<sup>17,18</sup> The described robust and

operationally facile methodology was specifically targeting functional 6-membered cyclic carbonate derivatives based on  $A_3$  and  $AB_2$  monomers, more specifically trimethylolpropane (TMP) and bis-MPA. An overview of the concept including the

- <sup>5</sup> polymerization to FAPCs is described in Scheme 1, and capitalizes on the isolation of two critical and reactive imidazole-functional intermediates 1 and 2. Conversion of 1 and 2 by alcohol-mediated imidazole displacement was utilized for synthesis of a diverse library of functional cyclic carbonates <sup>10</sup> based on TMP and bis-MPA (Figure 1).
- From initial screening experiments, we found that reaction of 1 eq. of TMP together with 2 eq. of CDI in acetone resulted in a spontaneous precipitation of TMP imidazole carbonate (TMPIC) 1. After a simple filtration, TMPIC 1 could be isolated as white
- <sup>15</sup> solid in 65% yield on an initial >60 gram scale. In contrast, treatment of bis-MPA with 2 Eq. of CDI in acetone under similar conditions, did not yield the corresponding cyclic carbonate product. Interestingly, increasing the ratio between CDI and bis-MPA to 3:1 in THF resulted in spontaneous formation of a white
- <sup>20</sup> solid. After a simple filtration procedure, tris-imidazole functional bis-MPA 2 (DIMIPA) was isolated in 67% yield on a close to 100 gram scale. <sup>1</sup>H-NMR spectra of TMPIC 1 and DIMIPA 2 can be seen in Figure 2a and Figure 3a, respectively. Both reactive intermediates could be stored on the bench for <sup>25</sup> months without any indication of degradation.
  - b) a) Feedstocks CDI Isolated Intermediates 2 - DIMIPA 1 - TMPIC 1) ROH ROH 58-84% 34-64% 2) SiO<sub>2,</sub> CsF<sub>cat</sub> NEt<sub>3 cat</sub> Functional Cyclic Carbonates 4a-e DBU ROP DBL Functional Polycarbonates p3a-p3e p4a-p4e
  - **Scheme 1.** Synthetic outline for accelerated synthesis of functional carbonate monomers and polymers from readily available TMP (a) and bis-MPA (b) feedstocks.
- <sup>30</sup> As an evident next step, a robust and selective postfunctionalization strategy was sought out for TMPIC **1** and DIMIPA **2** towards libraries of cyclic carbonates bearing relevant pendant functional groups. After initial screening of reaction conditions, we found that selective and near complete substitution

<sup>35</sup> of the imidazole group of TMPIC **1** with various alcohols was accomplished in acetone using 1 mol % of cesium fluoride (CsF), resulting in functional TMP-based cyclic carbonates **3a-e** (Scheme 1, Figure 1).

<sup>40</sup> **Figure 1.** Synthesized library of functional cyclic carbonates.

An illustrative example of the <sup>1</sup>H-NMR spectra of TMPIC **1** and products from reaction with propargyl alchohol into propargyl-TMP-carbonate **3b**, and final ROP polymerization into **p3b** are shown in Figure 2.

 $^{5}$  8.0 7.5 7.0 6.5 6.0 5.5 5.0 4.5 4.0 3.5 3.0 2.5 2.0 1.5 1.0 **Figure 2.** <sup>1</sup>H-NMR(CDCl<sub>3</sub>) spectra of (a) imidazole-TMP-carbonate 1, (b) propargyl-TMP-carbonate **3b**, and (c) poly propargyl-TMP-carbonate **p3b**.

A clear shift movement for the -CH<sub>2</sub> protons in the carbonate ring was found, from 4.25 and 4.38 ppm in **1** to 4.20 and 4.31 ppm in **3b.** Similar conditions for postfunctionalization by catalytic amounts of CsF when using DIMIPA **2** as precursor, did not produce corresponding cyclic carbonates in any acceptable yield. Interestingly, conversion of **2** was instead achieved using a one-<sup>55</sup> pot two-step procedure involving selective alcohol-induced displacement of the carboxylic imidazolyl group to produce an ester linkage, followed by a silica (SiO<sub>2</sub>) mediated ring-closing process in the presence of triethylamine (TEA) yielding bis-MPA based cyclic carbonate monomers **4a-e**, Scheme 1b and Figure 1. <sup>60</sup> The <sup>1</sup>H-NMR spectrum of **2** clearly shows a singlet corresponding to the -CH<sub>2</sub> bis-MPA protons in DIMIPA at 4.84 ppm, which upon propargyl alcohol induced substitution and carbonate ring formation to **4b**, moves into two doublets at 4.21 and 4.69 ppm, Figure 3a-b. Subsequent ROP of **4b** into **p4b** leads to a merging of the doublet signals, Figure 3c.

8.5 8.0 7.5 7.0 6.5 6.0 5.5 5.0 4.5 4.0 3.5 3.0 2.5 2.0 1.5 5 **Figure 3.** <sup>1</sup>H-NMR(CDCl<sub>3</sub>) spectra of (a) triimidazole- bis-MPAcarbonate **2**, (b) propargyl- bisMPA-carbonate **4b**, and (c) poly propargylbis-MPA- carbonate **p4b**.

Acetone was found to be the best solvent for the transformation of 1 and 2 to their respective cyclic carbonates, possibly due to a

- <sup>10</sup> stabilizing effect upon the formed cyclic carbonate monomers. Use of other organic solvents, such as dichloromethane and THF, was accompanied by significant side reactions like alcoholinduced ring-opening or oligomerization processes. Also, workup by silica filtration of the Et<sub>2</sub>O-diluted (1:1) crude reaction <sup>15</sup> mixtures prior to concentration *in-vacuo*, was proven essential to
- avoid oligomerization side-reactions, probably due to removal of residual CsF catalyst and imidazole byproduct. As seen in Figure 1, the described synthetic protocols enable the

construction of aliphatic cyclic monomers with high functional

- <sup>20</sup> group tolerance and selectivity. The displayed carbonates were carefully chosen to cover a range of relevant functionalities being bio- and bulky hydrophilic (MeO-PEG, **3c**) or hydrophobic (cholesterol **3e,4e**) as well as reactive. For the latter, cyclic carbonate monomers containing allyl-<sup>19</sup> (**3a,4a**), propargyl-<sup>20</sup>
- <sup>25</sup> (**3b,4b**), oxetane (**4d**) and furfuryl- (**4c**) pendant functionalities are envisioned highly valuable, due to well established postfunctionalization protocols by click reactions.<sup>5,21</sup> Also, the utility of oxetane<sup>22</sup>- and allyl<sup>23</sup>-functional polymers for efficient crosslinking into polymeric networks have been demonstrated.
- <sup>30</sup> All reactions were typically conducted on a 10 gram scale and monomers were isolated using standard chromatographic procedures. Without any further optimization, the overall yields of cyclic carbonates based on TMP (**3a-e**) were between 58 and 84 % and 34-64% for the bis-MPA based (**4a-e**). The purity of all
- <sup>35</sup> cyclic carbonates was corroborated by <sup>1</sup>H-NMR, <sup>13</sup>C-NMR and high-resolution mass spectrometry (HRMS), as can be found in the SI (S1-S24).

Satisfied with the simplicity and scalability of the CDI strategy, the functional cyclic carbonates were subjected to ROPs to

<sup>40</sup> deliver a library of FACPs using standard organocatalytic conditions.<sup>24</sup> The targeted molecular weight for all polymers was set to 10 kDa using pyrenebutanol as an initiator together with 5 mol% of 1:1 molar ratio between 1,8-Diazabicyclo-5.4.0-undec-7-ene (DBU) and 1-(3,5-bis(trifluoromethyl)phenyl-3-

45 cyclohexyl-2-thiourea (TU), Scheme 1 and Table 1.

4d	2	50	99	8.2	8.3	13.1	1.3

<sup>a</sup>All reactions were conducted in sealed vials, under an N<sub>2</sub>-atm. For all polymerization reactions, a 5 mol% catalytic loading of (DBU:TU) 1:1 and pyrenebutanol (PyrOH) initiator was used in dichloromethane

<sup>50</sup> solution, with a monomer concentration of 1M at room temperature.<sup>b</sup> Crude <sup>1</sup>H-NMR analysis.<sup>c</sup> SEC (DMF) with PMMA calibration.<sup>d</sup> <sup>1</sup>H-NMR end-group integration.<sup>e</sup>Based on measured monomer conversion.<sup>f</sup>DSC analysis.<sup>g</sup> Not detected due to formation of self-assembled aggregates.

- For the TMP-functional cyclic carbonates, the polymerization <sup>55</sup> was found to proceed to their maximum conversion within 16 hours, producing polycarbonates with bulky functionalities i.e. cholesterol **p3e** (42%) and PEG **p3c** (66%) to clickable propargyl **p3b** (89%). The <sup>1</sup>H-NMR spectrum of the latter can be seen in Figure 2c. Additionally, while <sup>1</sup>H-NMR analysis detail molecular <sup>60</sup> weights of **p3a-p3e** close to the targeted values the results from SEC were notably lower and with dispersities (Đ) ranging from 1.3-2.1, Figure S35 (SI). This is in line with previous observations by Hedrick and co-workers on ROP using similar monomers.<sup>11</sup> Interestingly, FAPC with pendant cholesterol group
- 65 p3e was found to form strong intermolecular agglomerations and thus unsuccessful detection by SEC. No further trials were attempted to increase the conversions of 3a-e.

In contrast, ROPs of bis-MPA carbonates **4a-d**, under similar conditions as for the TMP-based counterparts proceeded to high <sup>70</sup> conversions (89-99%) after 2 hours at room temperature. The <sup>1</sup>H-NMR spectrum of the purified propargyl functional bis-MPA

- polycarbonate **p4b** can be found in Figure 3c with distinct shift of the  $-CH_2$  upon ring-opening. Also, Table 1 and Figure s36 (SI) display the obtained molecular weights by SEC to which they <sup>75</sup> were in closer agreement to the theoretical ones and with lower
- observed Đ of 1.3-1.4. Thermal behavior of a number of both carbonates families bearing allyl- and propargyl- pendant groups was investigated by differential scanning calorimetry (DSC) (see SI for details). The polymers were found to display similar glass
- <sup>80</sup> transition temperatures, independently of the TMP or bis-MPA core carbonate structure. For both bisMPA- and TMP-functional PCs (**p3a** and **p4a**), the  $T_g$ 's were noted to be -12 °C, whereas the  $T_g$  of the corresponding propargyl functional PCs were +7 °C (**p3b**) and +9 °C (**p4b**), collected on the second heating scan at 10 <sup>85</sup> °C/min heating and cooling rate.

With respect to the envisioned potential biomedical applications of these functional polycarbonates, the cytotoxicity of the key reactive imidazole intermediates 1 and 2, the subsequent monomers and their corresponding polymers **p3a-e** and **p4a-e**  were tested according to ISO10993-5 procedures.<sup>25</sup> Human dermal fibroblasts (hDFs), being the most abundant cells in human dermis, were chosen for the initial cytotoxicity. This as the interaction between hDFs and biomaterials, such as wound dressings, is highly relevant in skin regeneration applications. Figure 4 details the cell viability of human dermal fibroblasts

(hDF) cultured in complete growth medium (CGM) extract of materials resulting in allyl functional PCs.

- Figure 4. Cell viability of hDF after culturing in extracts of cell culture coverslips coated with 0.1 mg of the intermediates 1 and 2, the monomers 3a and 4a and the polymers p3a and p4a. Extract of uncoated coverslips was employed as negative control (NC) to define cell viability of 1. Cell culture with addition of 0.1% Triton X-100 served as positive control (S (PC). Cell viability was evaluated after culturing in an incubator at 37 °C and 5% CO<sub>2</sub> in a humidified atmosphere for 24 h. The data represents the
- mean  $\pm$  standard deviation of three replicates.

Both carbonate monomers 3a and 4a and polymers (p3a and p4a) show no toxicity, i.e. no significant difference observed in the

- <sup>20</sup> metabolic activity of cells compared to that of negative control. The CGM extracts of intermediates (1 and 2) caused slight reactivity of cells indicated by the decrease of metabolic activity by about 20%. Complete evaluations of all the polycarbonates synthesized in this work (**p3a-e** and **p4a-d**) are included in the SI,
- <sup>25</sup> Figure s38-s41. All polycarbonates display low toxicity in elution tests or the direct contact tests, in which the hDF cells were cultured directly on the surface of polycarbonate coated coverslips (see SI for details).
- In conclusion, a simplified, robust and cost-efficient synthetic <sup>30</sup> strategy has been identified which unlocks the availability of an array of functional cyclic carbonate monomers at large scale. The methodology capitalised on facile use of CDI as a reagent and
- which together with simple AB<sub>2</sub> and A<sub>3</sub> monomers resulted in the isolation of stable and reactive imidazole intermediates on a 100 <sup>35</sup> gram scale. In contrast to previously published procedures, the
- current synthetic approach delivers functional aliphatic cyclic carbonate monomers and their corresponding FAPCs on large scales which open new opportunities in the design of functional carbonate materials with tailored applications. The relevance of
- <sup>40</sup> these functional polycarbonate materials for biomedical applications was highlighted by preliminary cytotoxicity studies using human dermal fibroblasts where no indications of adverse behavior were observed
