Herein we show that heating 2D Ti_3C_2 in air results in TiO_2 nanocrystals enmeshed in thin sheets of disordered graphitic carbon structures that can handle extremely high cycling rates when tested as anodes in lithium ion batteries. Oxidation of 2D Ti_3C_2 in either CO_2 or pressurized water also resulted in TiO_2 -C hybrid structures. Similarly, other hybrids can be produced, as we show here for $\text{Nb}_2\text{O}_5/\text{C}$ from 2D Nb_2C .

Among the myriad metal oxide/carbon materials, titania-carbon hybrids (TiO_2 -C) have attracted the most attention due to their superior performance in many applications. For example, nanocrystalline titania deposited on graphene is an excellent photocatalyst¹⁻⁴ and an outstanding electrode material in lithium-ion batteries (LIBs).⁵⁻⁸ To date, most of the synthesis techniques have been carried out using at least two main steps: graphene synthesis, followed by deposition of TiO_2 , with each step possibly consisting of multiple intermediate stages (e.g., solution deposition of amorphous TiO_2 followed by calcination to crystallize the oxide structure).⁸ In addition, an advanced one-step synthesis of a TiO_2 -graphene hybrid was achieved by solvothermal treatment of graphene oxide mixed with titania precursor solutions.⁹⁻¹²

Recently, we reported on the synthesis of a new family of two-dimensional (2D) transition metal carbides and carbonitrides, that we labeled MXenes.¹³⁻¹⁵ The latter have a composition of M_{n+1}X_n , where M stands for an early transition metal, X stands for carbon or nitrogen and $n = 1, 2, \text{ or } 3$.¹⁶ To date the following have been reported: Ti_2C , V_2C , Nb_2C , $(\text{Ti}_{0.5}\text{Nb}_{0.5})_2\text{C}$,

Fig. 1 Schematic of MXene oxidation and formation of oxide-graphitic disordered carbon hybrid structure.

Ti_3C_2 , Ti_3CN , $(\text{V}_{0.5}\text{Cr}_{0.5})_3\text{C}_2$, and Ta_4C_3 ,¹³⁻¹⁵ with Ti_3C_2 being the most investigated one.¹⁴

Herein, we report on the one-step synthesis of thin sheets of disordered graphitic carbon, decorated with oxide nanocrystals (Fig. 1) of anatase or niobia, Nb_2O_5 , by oxidizing 2D Ti_3C_2 or Nb_2C powders, respectively. In the Ti_3C_2 case, powders were flash oxidized in air at 1150 °C for 30 s. The resulting hybrid structure showed good performance as an anode material in LIBs at high rates. Similar structures were obtained by oxidizing Ti_3C_2 in CO_2 between 150 and 300 °C, or by a hydrothermal treatment in an autoclave at 150–250 °C in the 1–5 MPa pressure range.

The synthesis of the Ti_3C_2 powders is described in detail elsewhere.¹⁴ In brief, the Ti_3C_2 -based MXene powders were produced by etching Al from Ti_3AlC_2 powders in aqueous HF (50% conc.) solutions at room temperature, RT.¹⁴ The as-synthesized Ti_3C_2 surfaces are terminated by a combination of $-\text{OH}$, $=\text{O}$, and/or $-\text{F}$ groups.¹⁴ For simplicity, we will use " $\text{Ti}_3\text{C}_2\text{T}_x$ " to represent the as-synthesized surface terminated MXenes, where T_x stands for terminational functional groups. Free-standing paper was also fabricated by filtration of a colloidal solution of delaminated flakes of $\text{Ti}_3\text{C}_2\text{T}_x$ (referred to as d- $\text{Ti}_3\text{C}_2\text{T}_x$) in water. The details of the delamination process are summarized in the ESI† and ref. 17.

MXene powders or paper were placed in alumina boats, and flash oxidized at 1150 °C by rapidly (< 5 s) pushing the boat into the furnace's hot zone where the boat was kept at 1150 °C for 30 s, before being rapidly removed from the furnace in < 5 s. One of the challenges of flash oxidation is the difficulty in controlling the process, especially if ignition of the powders takes place. To explore

Fig. 2 Characterization of $\text{Ti}_3\text{C}_2\text{T}_x$ powders before and after flash oxidation in air at 1150°C for 30 s. (A) SEM image of typical as-synthesized multilayers $\text{Ti}_3\text{C}_2\text{T}_x$. (B) SEM image after oxidation. Top left inset is another SEM image at a different location for the same sample. (C) TEM image after oxidation. Inset is a high-magnification image of one of the anatase particles embedded in the amorphous carbon. (D) XRD patterns before and after oxidation. The blue diamonds denote anatase peak positions for (PDF#01-0562); squares denote Si peak positions which was used as an internal reference. (E) Raman spectra before and after oxidation; the stars represent anatase; D and G represent the positions of D and G bands of disordered graphitic carbon. (F) Nitrogen adsorption-desorption isotherms at -196°C for $\text{Ti}_3\text{C}_2\text{T}_x$ before and after oxidation. The inset shows a zoom of the $\text{Ti}_3\text{C}_2\text{T}_x$ isotherms along the Y-axis.

more controlled approaches MXene powders were: (i) held for 1 h in pure CO_2 at 150, 300, and 500°C and, (ii) heated hydrothermally in deionized (DI) water at 150, 200, and 250°C for 48 h, 8–20 h and 2 h, respectively, in an autoclave. Further details can be found in the ESI.†

The as-synthesized $\text{Ti}_3\text{C}_2\text{T}_x$ has a layered morphology resembling exfoliated graphite (Fig. 2A).¹⁸ After flash oxidation, oxide nanocrystals were observed to grow between, and at the edges of the layers (Fig. 2B). Energy dispersive X-ray analysis (EDX) showed them to be comprised of Ti and O. Several relatively large ($<0.5\ \mu\text{m}$) bi-pyramidal TiO_2 crystals (Fig. 2B) were observed as well, and their morphology suggests they are anatase. Similar nanometer-sized anatase bi-pyramids, with $\{101\}$ -plane faceting were reported by Čaplovičová *et al.*¹⁹ for TiO_2 derived from conventional mechanochemical synthesis and found to be highly photoactive. Note that nanocuboids were also observed in some scanning electron microscope (SEM) images (inset, Fig. 2B).

The cuboids are likely to consist of $\{001\}$ and $\{100\}$ facets.²⁰ The presence of the latter is not surprising, since the starting $\text{Ti}_3\text{C}_2\text{T}_x$ contained a significant fraction of $-\text{F}$ surface terminations which are known to stabilize the $\{001\}$ anatase surfaces.²¹ Sun *et al.*²² showed a significant improvement in photocatalytic activity under visible light for composites of anatase nanocrystals with exposed $\{001\}$ -facets on graphene sheets, as compared to pure TiO_2 nanosheets. The existence of these various morphologies demonstrates that MXenes can be used as facile precursors to create tailored morphologies. Further experiments,

however, are needed to tune the oxidation process to solely obtain a specific morphology.

Transmission electron microscope (TEM) images of oxidized $\text{Ti}_3\text{C}_2\text{T}_x$ (Fig. 2C) show that the nanocrystals are embedded in thin sheets. EDX of the sheets showed mainly C with some Ti, and O. The d -spacing between the atomic planes in the nanocrystals was measured from lattice fringes in TEM images (inset, Fig. 2C), and matched the (101) d -spacing of anatase, *viz.* $3.5\ \text{Å}$. The conversion of $\text{Ti}_3\text{C}_2\text{T}_x$ into nanocrystalline anatase and amorphous C was confirmed by X-ray diffraction (XRD) and Raman spectroscopy and the results are shown in Fig. 2D and E, respectively. The average anatase domain size, estimated from the XRD patterns is $\sim 60\ \text{nm}$ using the Scherrer formula.²³

The Raman spectrum of oxidized $\text{Ti}_3\text{C}_2\text{T}_x$ powders (top spectrum in Fig. 2E) showed a strong peak at $144\ \text{cm}^{-1}$ with a full width of half maximum (FWHM) of $14\ \text{cm}^{-1}$, together with three other peaks at 394, 513, and $635\ \text{cm}^{-1}$. These peaks can be assigned to the following anatase vibrational modes: $E_{g(1)}$, $B_{1g(1)}$, A_{1g} & $B_{1g(2)}$, and $E_{g(3)}$, respectively.²⁴ The peak positions and FWHM of $E_{g(1)}$ correspond to anatase particles with an average size of less than $15\ \text{nm}$.²⁴ The discrepancy between the average sizes obtained from XRD patterns and Raman spectra relates to the nature of each technique. In XRD, the average domain size obtained is averaged over a larger sampling volume; the values obtained from Raman spectra are more strongly affected by crystal lattice defects within the grains that lead to smaller scattering domains.²⁵ The two broad peaks between 1000 and $1800\ \text{cm}^{-1}$ are characteristic for the D- and

G-modes of graphitic carbon.²⁶ The D-band position and its FWHM were 1391 cm^{-1} and 225 cm^{-1} , respectively. The corresponding values of the G-band were 1596 cm^{-1} and 91 cm^{-1} . The ratio of the D- and G-band intensities, I_D/I_G , was ~ 0.78 . The broadening of G- and D-bands and the I_D/I_G ratio evidence highly disordered (amorphous) carbon similar to what has been reported for carbide-derived carbons (CDCs) fabricated at $200\text{ }^\circ\text{C}$.²⁷ The presence of carbon sheets covered by TiO_2 particles on the surface implies that the innermost Ti atoms in the MXene structure migrated outward to react with oxygen. This outward migration of Ti is similar to what has been observed previously during the oxidation of TiN .²⁸

The N_2 adsorption-desorption isotherms at $-196\text{ }^\circ\text{C}$ (Fig. 2F) show an increase in the specific surface area (SSA) after oxidation. The SSA estimated using the BET equation²⁹ for the oxidized sample was found to be $\sim 50\text{ m}^2\text{ g}^{-1}$, a factor of 5 greater than that of the as-synthesized MXene, which had a SSA of $10\text{ m}^2\text{ g}^{-1}$. This increase in SSA could be explained by the: (i) formation of nanometer-sized oxide particles and/or, (ii) opening or swelling of the layers during oxidation that allows the adsorbate to penetrate between the layers.

Flash oxidation of 2–4 μm thick d- $\text{Ti}_3\text{C}_2\text{T}_x$ “paper” in air at $1150\text{ }^\circ\text{C}$ for 30 s changed it from opaque black to translucent white. Interestingly, unlike the $\text{Ti}_3\text{C}_2\text{T}_x$ powders, oxidation of the paper did not result in the formation of crystalline phases detectable by XRD (Fig. S1A and S1B, ESI†). This can be explained by an easier oxygen access to each single or a few-layer-flakes of the MXene paper, resulting in more uniform oxidation and the formation of extremely thin and uniform TiO_2 particles. For multilayered stacked $\text{Ti}_3\text{C}_2\text{T}_x$ powders, a gradient of oxygen concentration (high outside the particle and lower inside) is expected. This in turn, results in formation of relatively large TiO_2 crystals (Fig. 2B) on the surface, similar to oxidation of the $\text{Si}_3\text{N}_4\text{-TiN}$ composite.²⁸

The characterization results for the isothermal oxidation of $\text{Ti}_3\text{C}_2\text{T}_x$ in CO_2 and hydrothermal oxidation in DI water are presented and discussed in detail in the ESI.† As shown in Fig. S2A (ESI†), anatase formation was observed by XRD when CO_2 was used at $150\text{ }^\circ\text{C}$ and higher temperatures. Note that the XRD patterns show the presence of some unreacted MXene along with the anatase after oxidation in CO_2 at $500\text{ }^\circ\text{C}$. The presence of disordered carbon was confirmed using Raman spectroscopy (Fig. S2C, ESI†). The morphology of the material oxidized using CO_2 (Fig. S2B, ESI†) is similar to what was observed after flash oxidation in air at $1150\text{ }^\circ\text{C}$. In the samples that were oxidized in CO_2 no bi-pyramidal crystals were observed.

The XRD patterns (Fig. S3, ESI†) after hydrothermal treatment in DI water also show incomplete oxidation and the co-existence of $\text{Ti}_3\text{C}_2\text{T}_x$ and anatase peaks. As shown in Fig. S4 (ESI†), the most uniform oxide morphology was obtained using this technique. No bare MXene sheets (similar to Fig. 2A) were observed by SEM (Fig. S4, ESI†), which could be due to the presence of unreacted MXene in the core and oxide particles on the surface (core-shell morphology).

To investigate the performance of the hybrid structures produced herein, we tested one of the samples that was produced

Fig. 3 Electrochemical performance of flash-oxidized $\text{Ti}_3\text{C}_2\text{T}_x$ powders in LIBs (A) CVs at a rate of 0.2 mV s^{-1} ; (B) effect of cycling on Li capacity at various rates.

by flash oxidation in air, as an electrode material in LIBs. Fig. 3A shows cyclic voltammograms (CVs) for flash-air oxidized $\text{Ti}_3\text{C}_2\text{T}_x$ powders. The reversible lithiation and delithiation peaks, respectively, at around 1.7 and 2.2 V vs. Li/Li^+ are quite close to what was reported for nanocrystalline anatase anodes.^{30,31} Similar peaks were observed for hydrothermally treated $\text{Ti}_3\text{C}_2\text{T}_x$ (Fig. S5, ESI†). As shown in Fig. 3B, reversible capacities of 220 mA h g^{-1} after 30 cycles at a cycling rate of C/18, 210 mA h g^{-1} after more than 200 cycles at C/3, and 155 mA h g^{-1} after 250 cycles at 1 C were obtained. These capacities are higher than those reported for anatase powder electrodes and comparable to those reported for anatase-functionalized hybrid structures of graphene sheets.⁸ Cai *et al.*³² reported a capacity of about 300 mA h g^{-1} at 1 C for TiO_2 -graphene composites within the same voltage window used here. The higher capacity they reported can be explained by the amount of graphene used in their composites which was more than double the carbon content in this work. It is worth noting that the maximum amount of carbon in our work after oxidation – assuming that no carbon is oxidized – is about 10 wt%. Said otherwise, if none of the carbon is oxidized and all the Ti is converted into TiO_2 , then the C: TiO_2 ratio by mass should be $\sim 1:10$.

When we tested our material at very high rates, *viz.* 40 C and 100 C, reversible capacities of 75 mA h g^{-1} and 45 mA h g^{-1} , respectively, were obtained after more than 250 cycles. These high cycling rates cannot be achieved with graphite electrodes and are better than what was reported for anatase. For example, Shin *et al.*³³ found that 5 to 10 nm anatase had no capacity at cycling rates of 30 C and 60 C, while nanoporous anatase had capacities of 77 mA h g^{-1} and 46 mA h g^{-1} at 30 C and 60 C, respectively. In that paper it was suggested that the good capacity at high cycling rates was due to interfacial storage.³³

As noted above, $\text{Ti}_3\text{C}_2\text{T}_x$ is just one member of the much larger MXene family. It follows that this work opens the door to numerous hybrid structures, of different nanocrystalline early transition metal oxides, on disordered graphitic carbon thin sheets. To prove the generality of the proposed approach, another MXene, *viz.* Nb_2CT_x ¹⁵ was oxidized by hydrothermal treatment in DI water at $150\text{ }^\circ\text{C}$ for 4 h and at $200\text{ }^\circ\text{C}$ for 2 h. The experimental details are similar to those described in the ESI† for $\text{Ti}_3\text{C}_2\text{T}_x$. As shown in Fig. S6A (ESI†), this procedure produced Nb_2O_5 after 4 h at $200\text{ }^\circ\text{C}$. Interestingly, no peaks related to crystalline oxides were observed in the XRD patterns after

treatment at 150 °C for 2 h. A broad Raman peak of Nb₂O₅ at around 700 cm⁻¹ (Fig. S6B, ESI†), similar to what was reported by Ghosh *et al.*³⁴ for Nb₂O₅ nanoforests, was observed in both cases. The co-existence of amorphous carbon and metal oxide can be seen in the Raman spectra after oxidation at 200 °C. In some locations, both carbon and niobia peaks were observed (Fig. S6B, ESI†), in others the carbon peak was not observed (dotted black spectrum in Fig. S6B, ESI†), which indicates that 200 °C may be too high if both oxide and carbon are desired. Further work is ongoing to fully convert Nb₂CT_x into nanosized oxides without sacrificing the carbon. For example, reducing the molar ratio of H₂O to MXene during hydrothermal treatment would yield a higher carbon content, similar to what was reported for binary transition metal carbides.³⁵ Based on previous work, it is reasonable to conclude that the Nb₂O₅/C composites made herein could possibly be quite useful in electrochemical capacitors³⁶ and LIBs.³⁷

As shown in Fig. S6C (ESI†), featherlike nano-particles were formed on the surfaces of the Nb₂CT_x sheets after hydrothermal oxidation at 150 °C. A few barrel-shaped oxide particles, with diameters of ~200 nm, were observed as well. Those barrel-shaped oxide particles became the dominant morphology after the 200 °C treatment (Fig. S6D, ESI†). It follows that the 150 °C treatment resulted in a hybrid structure of Nb₂CT_x, featherlike niobia and amorphous carbon. The 200 °C treatment resulted in mainly barrel-shaped nanocrystalline oxide particles and amorphous carbon, with a small amount of unreacted Nb₂CT_x.

In summary, flash oxidation of 2D Ti₃C₂T_x in air resulted in the formation of a hybrid structure of thin sheets of disordered graphitic carbon decorated with nanocrystalline anatase. The flash oxidized MXene powder showed higher capacities than nano-anatase in LIBs anodes at slow cycling rates (reversible capacities of 220 mA h g⁻¹ and 210 mA h g⁻¹ were obtained at C/18 and C/3, respectively), and an excellent capability to handle high cycling rates. At cycling rates of 1 C, 40 C, and 100 C, reversible capacities of 155 mA h g⁻¹ for 250 cycles, 75 mA h g⁻¹ for 300 cycles, and 45 mA h g⁻¹ for 300 cycles, respectively, were measured.

Oxidation in CO₂ and hydrothermal oxidation of Ti₃C₂T_x in DI water can also be used to produce hybrid structures of nanocrystalline anatase with amorphous C, but at significantly lower temperatures. Formation of the most uniform oxide particles was achieved by hydrothermal oxidation. However, when Ti₃C₂T_x powders were oxidized in CO₂ or hydrothermally, the resulting powders contained unreacted Ti₃C₂T_x, anatase and C. Similarly, Nb₂O₅ with amorphous C and unreacted Nb₂CT_x hybrid structures were obtained by hydrothermal treatment of the latter in DI water.

This work was supported by the National Science Foundation (DMR-1310245). MN is grateful to DAAD that partially supported him. Mr K-P. Schmitt at INM is acknowledged for his help in carrying out the hydrothermal treatments. BD was supported by NSF (CNS-0960061). VP thanks Prof. Eduard Arzt for his support and acknowledges funding from the German Federal Ministry for Research and Education in support of the nanoEES^{3D} project (03EK3013). CZ was supported by the Chinese Scholarship Council (CSC).
