# Rhodium(III) catalyzed olefination and deuteration of tetrahydrocarbazole†

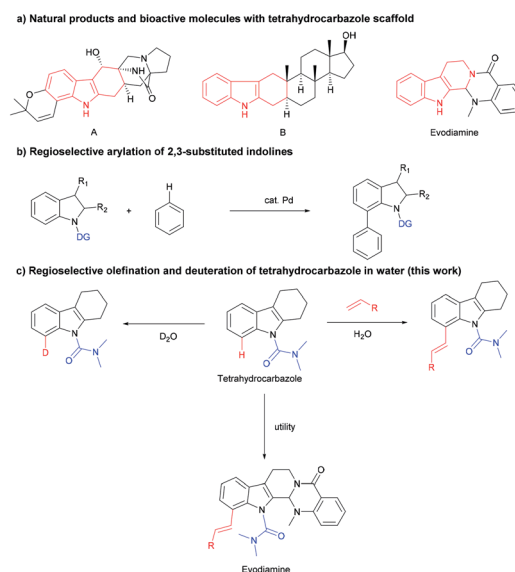

Wan Peng, Qiaohong Liu, Fucheng Yin, Cunjian Shi, Limei Ji, Lailiang Qu, Cheng Wang, Heng Luo, Lingyi Kong \* and Xiaobing Wang \*

The rhodium-catalyzed olefination and deuteration of tetrahydrocarbazoles in water with the aid of an *N,N*-dimethylcarbamoyl-protected group is presented. This olefination method features a broad substrate scope, good functional-group tolerance, and high efficiency in water. Practical applications of the protocol are illustrated by the synthesis of various evodiamine derivatives. As such, this environmentally friendly approach to directly modify natural products will attract much attention in academic and industrial research.

## Introduction

C–H functionalization strategies, which emerged as an increasingly powerful synthetic method, can functionalize the inactivated C–H bond or C–C bond directly, but provide high reaction efficiency and atom economy.<sup>1</sup> Rhodium catalysts have become quite popular in this field due to their high efficiency, good regioselectivity, and wide functional group tolerance.<sup>2</sup> The tetrahydrocarbazole framework is a common subunit in many bioactive compounds, and serves as the core to a wide variety of natural products, bioactive molecules and pharmaceuticals (Scheme 1a).<sup>3</sup> Tetrahydrocarbazole is one type of indole in which the C2 and C3 position were fused with a six-membered ring. Few studies on the C–H functionalization of tetrahydrocarbazole were reported, such as *N,N*-dimethylcarbamoyl-protected tetrahydrocarbazoles undergo directly oxidative to exclusively provide products from C(sp<sup>3</sup>)–H oxidation (2014).<sup>4</sup> However, indoles and indolines mediated by organocatalysts and transition metals have made fruitful and important progress.<sup>5</sup> For instance, alkenylation,<sup>6</sup> arylation,<sup>7</sup> alkylation<sup>8</sup> and others<sup>9</sup> of indoles and indolines at the C7 position have been described. The Oestreich group reported the palladium(II)-catalyzed arylation of 2,3-substituted indolines (Scheme 1b).<sup>10</sup> These results led us to explore whether this C8-functionalization strategy can be applied in tetrahydrocarbazoles.

The regioselective modification of natural products *via* the metal-catalyzed C–H bond activation strategy is difficult,<sup>11</sup> we demonstrated an efficient rhodium-catalyzed synthetic route for regioselective olefination of tetrahydrocarbazole in water. The present protocol using water as the solvent was compatible with a wide range of substituents on the tetrahydrocarbazole substrate. Furthermore, olefinated products could also be generated in a moderate yield at a lower reaction temperature in the developed system. It was also found that regioselective alkenylation of tetrahydrocarbazole derivatives followed by one-pot subsequent deprotection provides the desired product in good yield. In addition, synthetic applications of this novel alkenylation method were further demonstrated in an efficient modification of evodiamine.

On the other hand, isotopic labelling is of high significance for their utility, *e.g.* for investigating reaction mechanisms,<sup>12</sup> exploring the ADMET properties of existing drug candidates,<sup>13</sup> or in nuclear magnetic resonance spectroscopy<sup>14</sup> and mass spectrometry.<sup>15</sup> Since the FDA approved deutetrabenazine, which is the first deuterated drug in 2017,<sup>16</sup> deuterium has received unprecedented widespread attention. Versatile applications of deuterium-labelled compounds demand effective synthetic methods to regioselectively introduce deuterium atoms at specific positions. Hydrogen isotope exchange (HIE) assisted by metal-catalyzed C–H activation has become a widely utilized and elegant method for synthesizing isotopically labelled compounds, allowing direct and selective late-stage incorporation of deuterium or tritium (<sup>2</sup>H or <sup>3</sup>H).<sup>17</sup> Inspired by our above developed rhodium-catalyzed regio-olefination, we have also successfully achieved deuteration labelling of tetrahydrocarbazole with D<sub>2</sub>O, which serves as an economical deuterium source and solvent in this reaction.

## Results and discussion

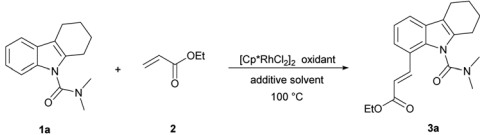

Initially, we started this idea using *N,N*-dimethylcarbamoyl-protected<sup>18a</sup> tetrahydrocarbazole **1a** and ethyl acrylate **2** as the template substrates. To our delight, the desired olefinated product **3a** was obtained in good yield (75%) under the

conditions of 5 mol% [Cp\*RhCl<sub>2</sub>]<sub>2</sub>, 20 mol% AgSbF<sub>6</sub>, and 3 equiv. of Cu(OAc)<sub>2</sub> in DCE at 100 °C for 12 h (Table 1, entry 1). Then, through evaluating different types of oxidants, Cu(OAc)<sub>2</sub> was found to be superior to the rest (entries 2–5).<sup>18a</sup> Thereafter, further screening of reaction solvents revealed that DCE showed the best performance in this reaction using AgSbF<sub>6</sub> as an additive (entries 6–9). Addition of AgNTf<sub>2</sub> in place of AgSbF<sub>6</sub> could improve the yield of **3a** (entry 10).<sup>18b</sup> Further shortening or extending the reaction time offered no improvement to the yield (Table S1 in the ESI†). Moreover, decreasing the reaction temperature to 80 °C was beneficial to the olefination, and the product **3a** was obtained in 93% yield (entry 11 and Table S2†). To our delight, we accidentally found that the reaction proceeded smoothly in water without obvious decrease in the yield (entry 12). Considering the cost and environmental factor, we decided to employ the reaction using water as the solvent. Lowering the amount of catalyst, oxidant, additive and ethyl acrylate (Tables S3–S5†), we got the final optimized reaction conditions (entry 13). In addition, we also found that this reaction could proceed and provided the desired alkenylated product **3a** in moderate yield (78%) when the temperature was decreased to 60 °C (entry 14). **3a** was observed with a yield of 10% when the reaction was carried out without an oxidant (entry 15). The reaction hardly happened without an additive (entry 16). These results showed that the oxidant and additive had crucial roles in this olefination.

With the optimal reaction conditions established, we next explored olefination with a variety of substituted tetrahydrocarbazoles (Table 2). For C6-substituted substrates, moderate to good yields were obtained with both electron-donating (**3b**, **3c**) and electron-withdrawing groups (**3d–3h**) compared to C5-substituted substrates (**3i**, **3j**) and C7-substituted substrates (**3k–3m**). It is noteworthy that the halogen groups such as F (**3e**, **3n**) and Cl (**3f**) performed well in C8-olefination. In comparison with substrates bearing electron-donating groups (–CH<sub>3</sub>, –C(CH<sub>3</sub>)<sub>3</sub>), those bearing electron-withdrawing groups (–F, –Cl and –Br) decreased the overall yields, which might imply an electrophilic activation pattern. We were pleased to find that tetrahydrocarbazoles containing a methyl group at the six-membered ring were olefinated in good yields, with good selectivity (**3o–3t**) and did not affect the efficiency of this process. The size of the aliphatic ring was well tolerated (**3u**). The presence of an additional piperidine ring was also tolerated (**3v**, **3w**), providing a moderate yield (67%). Notably, a fluzoxazone analogue was embedded in drug candidates in excellent yield (**3x**). Interestingly, medicinally useful carbazole was alkenylated to give the *mono*-olefinated product **3y** in good yield.

We further investigated whether the protocol could be applied to a wide range of olefin coupling partners (Table 3). Methyl acrylate (**2a**), phosphonate (**2b**), styrene (**2c**), 3-fluorostyrene (**2d**) and phenyl vinyl sulfone (**2e**) were effectively coupled with **1u** to furnish the corresponding products (**3aa**, **3ab**, **3ac**, **3ad** and **3ae**) in moderate to good yields (47–89%), respectively. In addition, maleimide was also successfully coupled in moderate yield (**3af**).

<sup>a</sup> **1a** (0.1 mmol, 1 equiv.), **2** (2 equiv.),  $[\text{Cp}^*\text{RhCl}_2]_2$  (4 mol%),  $\text{AgNTf}_2$  (20 mol%),  $\text{Cu}(\text{OAc})_2$  (2 equiv.),  $\text{H}_2\text{O}$  (1.0 mL), 80 °C, 12 h. <sup>b</sup> Data are reported as isolated yields.

We have established a method for the olefination of tetrahydrocarbazole in water. This approach led us to explore whether this functionalization strategy could be applied for deuteration. We studied the selective deuteration process of tetrahydrocarbazole with substrate **1u** as the initial substrate. On the basis of olefination conditions, different deuterium-containing solvents ( $\text{D}_2\text{O}$ ,  $[\text{D}_4]$ -methanol,  $[\text{D}_1]$ -TFA,  $\text{CDCl}_3$ ) were tested (Table S6 in the ESI†).<sup>19</sup> To our delight, **1u** was proceeded with 5 mol%  $[\text{Cp}^*\text{RhCl}_2]_2$ , 20 mol%  $\text{AgNTf}_2$ , and 3 equiv. of  $\text{Cu}(\text{OAc})_2$ , providing deuterated product **5u** in 90% yield. This result was very meaningful as  $\text{D}_2\text{O}$  acted as not only a deuterium provider, but the solvent of the reaction, and encouraged us to explore the utility of this method. Gratifyingly, most substrates were compatible, which greatly enhanced the scope of the method (Table 4). Under the reaction condition, the  $\text{CH}_3$ -,  $\text{CH}_3\text{O}$ -, F-, Cl- and Br-substituted at the C6-position (**5b**, **5d**–**5e**, **5g**) could be smoothly deuterated. The F-substituent at C-5 (**5i**, **5n**) had little influence on the results for the deuteration

<sup>a</sup> **1u** (0.1 mmol, 1 equiv.),  $[\text{Cp}^*\text{RhCl}_2]_2$  (5 mol%),  $\text{AgNTf}_2$  (20 mol%),  $\text{Cu}(\text{OAc})_2$  (3 equiv.),  $\text{D}_2\text{O}$  (0.5 mL), 80 °C, 12 h. <sup>b</sup> Deuterium incorporation at the aromatic position was determined by  $^1\text{H}$  NMR spectroscopy. <sup>c</sup> Data are reported as isolated yields.

rates and gave more than 99% D incorporation. Carbazole was also shown to exhibit high levels of reactivity.

Next, the practicality of this protocol was examined. As shown in Scheme 2a, the reaction was scalable in normal reaction equipment and gave the olefinated products (52% and 80%) using water and DCE as solvent, respectively. Compounds

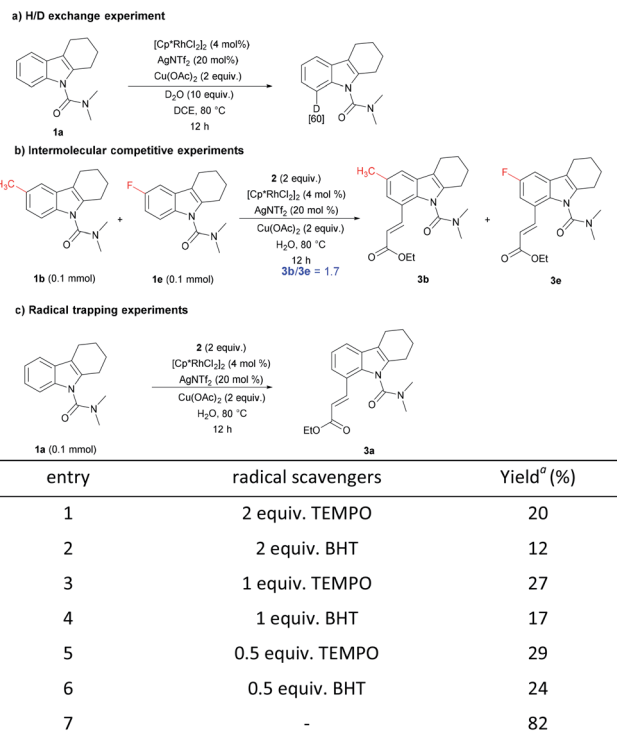

Scheme 2 The utility of this method.

**3u** and **5y** were further deprotected under basic conditions to provide the corresponding products in 75% and 89% yield (Scheme 2b). In order to improve the synthetic utility of this protocol and avoid the tedious purification, we next pursued the direct synthesis of **3u'** by a one-pot method. Following rhodium-catalyzed olefination, the product was filtered out through a celite pad without additional purification. Then, the directing group was removed, and the desired product **3u'** was obtained in 71% yield (Scheme 2c), which further demonstrated the applicability of the method.

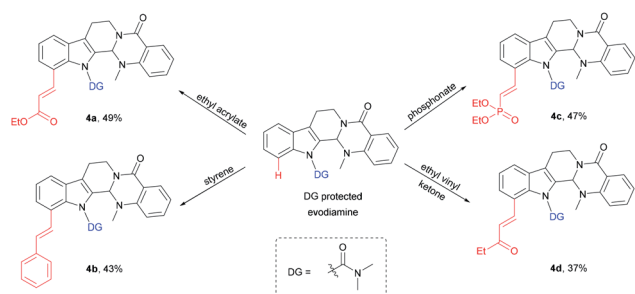

An application of this novel methodology on the olefination of a more complex natural product evodiamine was tested (Scheme 3). The method was used to directly modify evodiamine and obtain evodiamine derivatives (**4a–4d**) with moderate yields.

To perceive the reaction mechanism, the following experiments were performed (Scheme 4).<sup>20</sup> First, *N,N*-dimethyl-carbamoyl-protected tetrahydrocarbazole **1a** under the reaction condition with 10 equiv. of D<sub>2</sub>O gave a C8-deuterated compound in 60%, indicating the reversibility of the C–H activation step. Next, an intermolecular competition experiment between electronically diverse tetrahydrocarbazoles led to the conclusion that an electron-rich substrate tended to react at

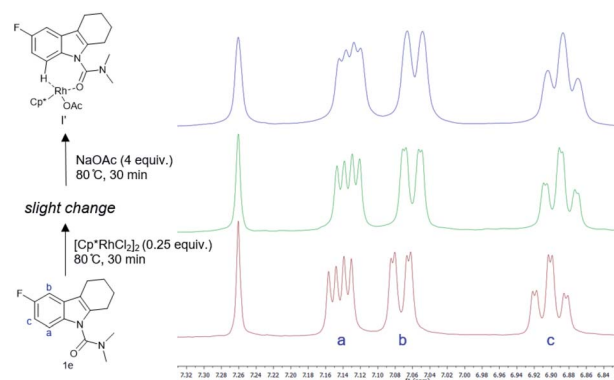

Scheme 4 Mechanistic studies. <sup>a</sup> Data were obtained by <sup>1</sup>H NMR analysis with CH<sub>2</sub>Br<sub>2</sub> as reference. BHT = 2,6-di-*tert*-butyl-4-methylphenol, TEMPO = 2,2,6,6-tetramethylpiperidinoxy.

a higher rate. Subsequently, radical trapping experiments were explored. The yield of the desired compound decreased remarkably with the addition of the radical scavengers. Adding different proportions of free radical scavenger had almost no obvious change, and the yield was similar to the variable without adding oxidant. These results suggest that a radical should not be involved in the reaction and the added radical scavengers may destroy the properties of the oxidant copper acetate.

To develop a better understanding of the catalyst reaction state, on-line <sup>1</sup>H NMR experiments were carried out (Fig. 1). There was a slight change in the peak position of the substrate

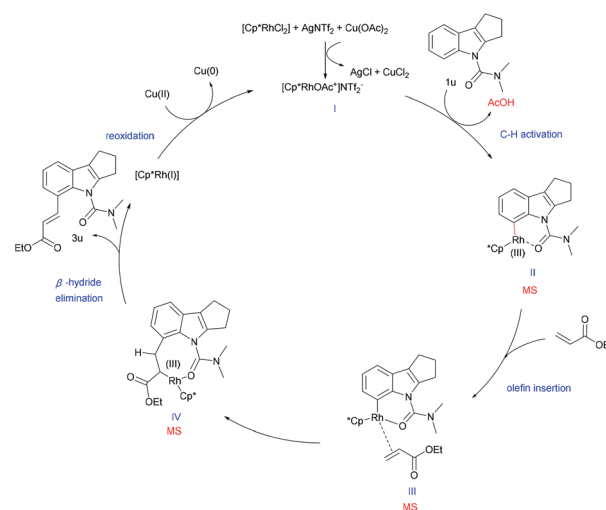

Scheme 3 Modification of natural product evodiamine.

Fig. 1 Real-time on-line <sup>1</sup>H NMR monitoring of substrate-Rh-NaOAc interaction.

after adding the catalyst  $[\text{Cp}^*\text{RhCl}_2]_2$ . After adding sodium acetate, the peak shape of the substrate changed significantly.<sup>21a,b</sup> We speculate that the -OAc group promotes the weak coupling between the catalyst and the substrate, resulting in the change of the peak, producing the intermediate **I'**. These data indicated that intermediate **I'** may be the reaction state of the catalyst in the system. Considering that C8-olefination could occur in DCE using  $\text{Ag}_2\text{CO}_3$  as the oxidant, the reaction of **1e** in  $\text{CDCl}_3$  was monitored with  $^1\text{H}$  NMR spectroscopy.<sup>21c,d</sup> The  $^1\text{H}$  NMR analysis experiments were carried out in the same clean NMR tube in a continuous sequence. As shown in Fig. 2, the signals of **1e** and **2** disappeared while that of product **3e** increased with time. The reaction rate slowed down after 3.5 h. The contrast spectra of **3e** (top trace of Fig. 2) indicated nearly no byproduct formation.

Based on the above mechanistic studies and precedent literature,<sup>22</sup> we have proposed a tentative catalytic cycle for this reaction (Scheme 5). We presume that, initially, a more active cationic rhodium complex **I** is formed with  $\text{AgNTf}_2$  and  $\text{Cu}(\text{OAc})_2$ , followed by the C–H functionalization of substrate **1u** to generate the six membered rhodacycle **II**. A subsequent olefin insertion step provides intermediate **III**. Then, rhodacycle **III** provides the eight-membered **IV**, which undergoes  $\beta$ -hydride elimination to continue the catalytic cycle and produces the desired olefinated product. Meanwhile, the  $\text{Rh}^{\text{III}}$  complex regenerates  $\text{Rh}^{\text{I}}$  by reoxidation, thereby completing the mechanistic cycle. Besides, the presence of intermediates (**II** and **III** or **IV**) was also detected by ESI-MS supporting the plausibility of our reaction hypothesis (see the ESI†).

Scheme 5 A plausible mechanistic cycle.

## Conclusion

In summary, we have reported an efficient, selective, direct olefination and deuteration of tetrahydrocarbazoles attached to the *N,N*-dimethylcarbamoyl-protected group by rhodium catalysis. Substitutions at various positions of the tetrahydrocarbazoles were tolerated. Easy removal of the template and gram-scale reaction demonstrate the extensive utility of this protocol. This method has been successfully applied to the natural product evodiamine. In this olefination reaction, water is an efficient solvent. The deuterium reaction uses  $\text{D}_2\text{O}$ , which is desirable and atom economical, as the deuterium source. Exclusive site selectivity, functional group tolerance, and late-stage modifications are the important practical features. We believe that the new facile and green approach for modifying natural products could pave a new way in drug discovery.
