Molecular AND logic gates 1, 3, 5 and 7, which are designed according to principles of photoinduced electron transfer (PET) switching, respond to co-existing *Candida antarctica* lipase B and H⁺ (and Na⁺).

Molecular logic-based computation^{1–4} requires gates to process and store information. Besides its ability to operate in biocompatible micrometric spaces, the diversity of information available to molecular logic distinguishes it from its semiconductor cousin which employs voltage information only. For instance, the inputs feeding gates can take the form of physical entities (e.g. light dose,⁵ temperature⁶), chemical species (e.g. atomic,¹ molecular⁷) and biochemical species (e.g. nucleotides,⁸ enzymes³). However, there are hardly any examples of combined atomic and enzyme inputs in the literature, if at all.

Fluorescent PET switches grew out of the sensing literature.⁹ Although atomic inputs were present from the beginning,¹⁰ protein inputs were incorporated only recently.¹¹ Even these covered only some receptor- and transport-proteins.[§] A way to incorporate hydrolase enzymes was described by Ojida *et al.*¹² and us.¹³ Here, a fluorescent PET system based on a ‘fluorophore-spacer-amine’ format relied on the upward shift of the amine’s pK_a value by ~ 2 pH units upon hydrolyzing a neighbouring ester into a carboxylate anion. Now we show how such systems can serve as fluorescent molecular logic gates driven by atomic ions, H⁺ and Na⁺, and a hydrolase enzyme, *Candida antarctica* lipase B (CALB).

Logic gate **1** is synthesized by nucleophilic substitution of 4-bromomethyl-7-methoxycoumarin with sarcosine ethyl ester. **1** is a typical fluorescent PET ‘off-on’ switch of the ‘fluorophore-spacer-receptor’ format⁸ with H⁺ being the input. By itself, the 7-methoxycoumarin fluorophore has no significant interaction with H⁺ in the pH range of our experiments since it lacks a

Fluorescent molecular logic gates based on photoinduced electron transfer (PET) driven by a combination of atomic and biomolecular inputs^{†‡}

suitable receptor.¹⁴ **1**’s pH-dependent fluorescence intensity (I_F) is analysed according to eqn (1)¹⁴ to give $pK_a = 3.6$. The fluorescence quantum yields are $\Phi_{F_{max}} = 0.97$ and $\Phi_{F_{min}} = 0.02$.

$$\log[(I_{F_{max}} - I_F)/(I_F - I_{F_{min}})] = \text{pH} - pK_a \quad (1)$$

The hydrolysis product of **1**, which is **2** (shown in Scheme 1 as the carboxylate form owing to the operational pH range of 6–10 for gate tests), is tested similarly and yields $pK_a = 6.7$. The fluorescence quantum yields of **2** are $\Phi_{F_{max}} = 0.48$ and $\Phi_{F_{min}} = 0.01$. The lower $\Phi_{F_{max}}$ value of **2** (*cf.* **1**) is due to the three-atom linker folding the carboxylate unit over the fluorophore¹⁵ to allow intramolecular interaction in the excited state.¹⁶ All these parameters for all compounds studied are collected in Table 1.

1 was subjected to an enzyme screen to see which enzyme would hydrolyze **1** most efficiently to **2** at pH 7 (Fig. 1). CALB was found to be the most efficient, which is gratifying since CALB is known¹⁷ to hydrolyze a variety of esters over a wide pH range. Additionally, it was found that the hydrolysis reaction could be most conveniently followed by the fluorescence emission signal (Fig. 1). Thus we realize that **1** becomes a ‘fluorophore-spacer₁-receptor-spacer₂-enzyme substrate’ system.

The fluorescence spectra of **1** at pH 6 and 10 with/without CALB exposure for 30 min are shown in Fig. 2a. The AND logic response of the fluorescence signal is clear since both H⁺ and

Porcine pancrease grade II, 36. Pig liver esterase, 37. *Penicillium* acylase. Data point 39 is pure **2**.

CALB are needed to elicit a 'high' fluorescence response from **1**. When exposed to CALB at pH 6, **1** gradually hydrolyzes to **2** and shows a gradual increase in fluorescence intensity. The **1**–CALB interaction is governed by a Michaelis constant K_M of $1.9 \times 10^{-5} \text{ M}$ and V_{\max} value of $5.0 \times 10^{-10} \text{ M s}^{-1}$. These values are obtained by applying eqn (2) to convert the rate of change of fluorescence intensity into the rate of change of the product **2** concentration, followed by the application of eqn (3).¹⁸

$$V = \frac{d(2)}{dt} = \left[\frac{dI_F}{dt} \right] \cdot (1)_{t=0} / \left[\left(\frac{\Phi_{F_2}}{\Phi_{F_1}} - 1 \right) \cdot I_{F_{t=0}} \right] \quad (2)$$

$$1/V = \left[\left(\frac{K_M}{V_{\max}} \right) / (1) \right] + 1/V_{\max} \quad (3)$$

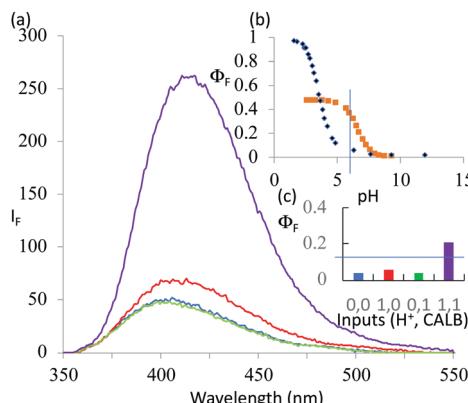

Fig. 2 (a) Fluorescence spectra of $7.3 \times 10^{-6} \text{ M}$ **1** under stimulation with H^+ and CALB inputs for 30 min in water:methanol (4:1, v/v) ($\lambda_{\text{exc}} = 326 \text{ nm}$) at 20°C where 'high' and 'low' H^+ correspond to pH 6 and 10 respectively and 'high' and 'low' CALB correspond to $7.1 \times 10^{-6} \text{ M}$ and 0 M respectively. Input states (H^+ , CALB) of (0,0), (1,0), (0,1) and (1,1) are shown in blue, red, green and purple respectively. The 'high' level of H^+ input, 10^{-6} M , is chosen from the pH value at which maximum discrimination of the fluorescence signals between **1** and **2** is seen in (b). (b) Φ_F of **1** (black) and **2** (orange) as a function of pH. (c) Pictorial version of truth table showing Φ_F values extracted from (a). Output threshold chosen at $\Phi_F = 0.13$.

It is to be noted that the enzyme reaction is irreversible under our experimental conditions so that the logic device is suitable only for single-use situations. Such single-use situations are commonly present in the medical diagnostics sphere, as seen with two¹⁹– or three²⁰ (Scheme 1).

Owing to the diversity available in inputs, outputs, power supplies and devices within molecular logic, several routes to reconfigurability have become available.² However, we are not aware of any cases in the primary literature where logic is reconfigured by changing molecular configuration. Since the enantiodiscrimination of enzymes is well-established, we now have an opportunity to present such an approach.

The enantiomeric pair of logic gates 3 \uparrow and 5 \uparrow arise from a synthesis analogous to that of **1**. The hydrolysis products of these are **4** and **6** respectively, although only **6** was available for pK_a determination. pK_a values are measured for these compounds with the aid of eqn (1), as done for **1** and **2**. The values obtained for **3**, **5** and **6** are 4.5, 4.5 and 7.1 respectively. The pK_a value of **4** is expected to be the same as that found for its opposite enantiomer **6**, i.e. 7.1.

As seen in Fig. 3a, the fluorescence spectra of **3** at pH 6 and 10 with/without CALB exposure for 30 min correspond to a PASS 0 logic action. On the other hand, Fig. 3b shows an AND logic action for **5**. **3** and **5** differ in the configuration of the functional groups around the asymmetric carbon. Thus, logic reconfiguring is achieved by changing the molecular configuration of the device. At pH 6, K_M values are not very different, i.e. 1.1×10^{-5} and $1.6 \times 10^{-5} \text{ M}$, for **3** and **5** respectively. However, V_{\max} values differ significantly, i.e. 7.5×10^{-9} and $9.7 \times 10^{-8} \text{ M s}^{-1}$, as a result of CALB's enantioselectivity.

We have explored the modularity of our design by building a prototype 3-input AND gate 7 \uparrow of the 'receptor₁–spacer₁–fluorophore–spacer₂–receptor₂–spacer₃–enzyme substrate' format,

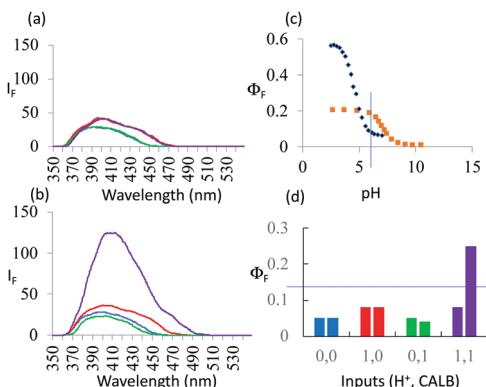

Fig. 3 (a) Fluorescence spectra of 7.3×10^{-6} M **3** under stimulation with H^+ and CALB inputs for 30 min in water:methanol (4:1, v/v) ($\lambda_{\text{exc}} = 326$ nm). 'High' and 'low' input levels are as in Fig. 2. Input states are coloured as in Fig. 2. The 'high' level of H^+ input, 10^{-6} M, is chosen from the pH value at which maximum discrimination of the fluorescence signals between **5** and **6** is seen in (c). (b) Same as in (a) but for **5** instead of **3**. (c) Φ_F of **5** (black) and **6** (orange) as a function of pH. (d) Pictorial version of truth table showing Φ_F values extracted from (a) and (b). Left-hand bars of each pair correspond to **3** whereas right-hand bars correspond to **5**. Output threshold chosen at $\Phi_F = 0.13$.

which is driven by CALB, H^+ and Na^+ . The sensitivity of logic gate 7's fluorescence to Na^+ , *cf.* that of **1**, arises from the new benzo-18-crown-6 ether functional group within **7**.

7 is synthesized by reacting a known anthracene-crown ether conjugate²¹ with sarcosine ethyl ester. Its AND logic behaviour is shown in Fig. 4a and c. Its $pK_a = 5.8$ (at 1.0 M Na^+) in water:DMSO (1:1, v/v). **8**, the hydrolysis product of **7**, has $pK_a = 8.8$ under the same conditions. The $\log \beta_{\text{Na}^+}$ values for **7** and **8** are 0.7 and 0.8 respectively (at pH 4.5). The **7**-CALB interaction is

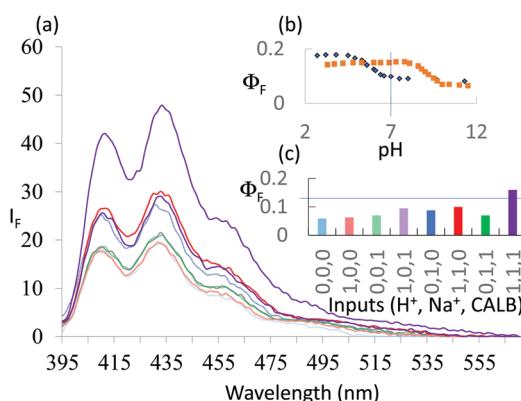

Fig. 4 (a) Fluorescence spectra of 7.3×10^{-6} M **7** under stimulation with H^+ , Na^+ and CALB inputs for 30 min in water:DMSO (1:1, v/v) ($\lambda_{\text{exc}} = 378$ nm). 'High' and 'low' input levels for H^+ and CALB are as in Fig. 2, except that 'high' H^+ is 10^{-7} M, with 'high' and 'low' Na^+ levels being chosen as 1.0 and 0 M respectively. Input states are coloured as in Fig. 1 for 'high' Na^+ , while those with 'low' Na^+ are shown in the same colours but with 50% transparency. The 'high' level of H^+ input, 10^{-7} M, is chosen from the pH value at which maximum discrimination of the fluorescence signals between **7** and **8** is seen in (b). (b) Φ_F of **7** (black) and **8** (orange) as a function of pH in the presence of 1.0 M Na^+ . (c) Pictorial version of truth table showing Φ_F values extracted from (a). Output threshold chosen at $\Phi_F = 0.13$.

characterized at pH 7 and at 1.0 M Na^+ by $K_M = 2.2 \times 10^{-6}$ M and $V_{\text{max}} = 7.5 \times 10^{-10}$ M s⁻¹. This proof of principle study does not examine selectivity issues with respect to other metal ions.

We conclude that the fluorescent PET sensing/switching design is a useful starting point for constructing tailored molecular logic systems which employ mixed inputs from the chemical and biological spheres, especially when the latter concerns a hydrolase enzyme. Such systems are unique when compared with previously developed AND and other logic gates.^{2,3} This approach also allows demonstration of logic reconfiguring by changing the molecular configuration of the logic device.

We acknowledge the Department of Employment and Learning, Northern Ireland and T. J. Lively for support and help.

Note added in proof: Fluorescent PET probes for some oxidoreductase proteins are also available.^{8,22}
