This article can be cited before page numbers have been issued, to do this please use: F. della Sala, B. Doerner and S. Webb, *Org. Biomol. Chem.*, 2025, DOI: 10.1039/D5OB01226K.

This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

## ARTICLE

## Modular synthesis of zinc(II)-bis(triazole) recognition sites for the conformational control of foldamers

Flavio della Sala,<sup>a,b</sup> Benedicte Doerner,<sup>a,b</sup> and Simon J. Webb<sup>\*,a</sup>(Received 00th January 20xx,  
Accepted 00th January 20xx)

DOI: 10.1039/x0xx00000x

Zinc(II) bis(triazolyl)(pyridyl)amine (Zn(BTPA)) complexes on the end of  $\alpha$ -amino-*iso*-butyric acid (Aib) foldamers are able to transfer chirality from bound anions to the helical foldamer body. Zn(BTPA) could be obtained by simple synthetic methodology that allowed a range of functional groups to be installed around the binding site, exemplified with a fluorophore, a macrocyclic bridge and Aib itself. Changing functional group did not prevent chiral ligands from controlling foldamer conformation, although differences in complexation kinetics and equilibria were observed. Addition of acetate gave a 2:1 foldamer:acetate intermediate at sub-stoichiometric acetate; a similar intermediate was implied during titration with Boc-Pro. A bulkier phosphate ligand or a more sterically hindered site did not form similar intermediates. The modular construction of Zn(BTPA)-capped foldamers will allow these conformational relays to be installed in a wide range of biomimetic constructs.

## Introduction

Metal ions play important roles in enzyme active sites and during ligand binding to proteins. Zinc(II) for example can control protein shape by coordinating to side chains on different secondary structures, as found in the zinc finger motif. The resulting structurally defined regions are critical for protein-DNA binding.<sup>1</sup> Metal ions in proteins can also directly bind to cognate ligands, e.g. some calcium(II)-dependent animal lectins form direct coordination links between the sugar hydroxyls and bound calcium(II).<sup>2</sup> Ligand binding to metal ions in proteins can then induce global conformational changes, with the binding of oxygen to haemoglobin one of the best known examples.<sup>3</sup> Protein folding into geometrically defined pockets around the metal ions are important for these proteins to function.

Folded oligomers (foldamers) can coordinate to metal ions,<sup>4,5</sup> with some foldamers shown to mimic metalloprotein structure, including the zinc finger motif.<sup>6,7</sup> The metal ions can also become catalytic centres on the foldamers and/or provide locations for ligand binding. Ligand-induced conformational change, as observed in haemoglobin, can also be replicated. Upon binding, some ligands will perturb the conformational landscape of dynamic foldamers,<sup>8-11</sup> which are a type of foldamer that undergo rapid conformational interchange.  $\alpha$ -Amino-*iso*-butyric acid (Aib) foldamers are rod-like dynamic foldamers that can undergo rapid long range (> 1 nm) conformational change in response to external stimuli. Their

chief conformational populations are  $3_{10}$  helices that have either a right-handed (*P*) or left-handed (*M*) screw-sense. Ligand binding at one terminus can cause these Aib foldamers to undergo end-to-end conformational change, which changes the proportion of *P* to *M* helices. These changes can be expressed as the helical excess, h.e., which is the fractional excess of *P* helix over *M* helix (h.e. =  $([P] - [M]) / ([P] + [M])$ ); this can be calculated from representative NMR spectra.<sup>12</sup> This simple *P* vs. *M* conformational landscape has led to Aib foldamers being used to mimic aspects of biological signal transduction, particularly how ligand recognition can initiate conformational change across multi-nanometre distances. To mediate ligand recognition, Zn(II) and Cu(II) complexes can be placed at one end of the Aib foldamers.<sup>9,13-15</sup> Like related complexes in the literature,<sup>16-21</sup> they bind chiral anions, including carboxylates.<sup>9a</sup>

Old design: BQPA-capped foldamer Zn(1)·2ClO<sub>4</sub>

**Figure 1.** Reported foldamer Zn(1)·2ClO<sub>4</sub> bearing the bis(quinolyl)(pyridyl)amine (BQPA) binding pocket.<sup>15</sup> Perchlorate anions omitted for clarity.

The M(II)-bis(quinolyl)(pyridyl)amine (BQPA, Figure 1) binding site is the best to date for turning ligand chirality into a change in the *P*:*M* screw-sense ratio of an Aib foldamer. Its effectiveness has been ascribed to the steric bulk of the quinolyl arms and the “propeller” conformation they adopt.<sup>22</sup> Both Zn(II) and Cu(II) complexes are effective. Foldamers capped with Zn(II)-BQPA could sense the enantiomeric excess (ee) of

## ARTICLE

## Journal Name

scalemic mixtures of chiral carboxylates,<sup>22</sup> due to rapid ligand exchange at the Zn(II) site.<sup>15</sup> A Cu(II)-(BQPA) recognition site provided a synthetic receptor that responded to chiral carboxylates (the input signal) by undergoing a conformational change either in solution or deep into lipid bilayers.<sup>9a</sup>

## New design: BTPA-capped foldamers

**Figure 2.** Foldamers  $\text{Zn}((R)\text{-}2)\cdot 2\text{ClO}_4$  bearing the bis(triazolyl)(pyridyl)amine (BTPA) binding pocket, which is constructed in a modular fashion from different azides. Perchlorate anions are omitted for clarity.

These previous Aib foldamers with BQPA have a metal ion-chelating pocket that is symmetric and unfunctionalised,<sup>13-15</sup> unlike the naturally asymmetric binding pockets of proteins. We wished to retain the desirable recognition characteristics of BQPA but add functionality to the “arms” around the binding site. BQPA itself was difficult to modify and its relatively poor stability also required it to be added last during synthesis.

To better replicate metal ion containing binding pockets in proteins, simpler methods were needed to introduce functionality and decrease symmetry. To this end, we have explored the use of copper-catalysed alkyne-azide cycloaddition (CuAAC) reactions to create metal ion binding pockets<sup>23,24</sup> (Figures 2 and 3) that are flanked by selected substituents. The use of CuAAC allows simple modification of the synthetic route to provide either symmetrical or unsymmetrical metal ion binding pockets.

**Figure 3.** Foldamer  $\text{Zn}((R)\text{-}6)\cdot 2\text{ClO}_4$  bearing the (pyridyl)(triazolyl)(pyridyl) (PTPA) binding pocket with different binding arms. Perchlorate anions are omitted for clarity.

To study the effect of these binding sites at the N-terminus of Aib foldamers, we placed the recently reported (*R*)-1-(trifluoromethyl)-ethylamido (*R*)-TFEA reporter group at the C-terminus.<sup>25</sup> This group provides <sup>19</sup>F NMR spectroscopic reports on changes in the conformational populations of Aib foldamers that are induced by chiral anionic ligands binding to the Zn(II) (such as carboxylates or phosphates, Figure 4).<sup>26</sup>

**Figure 4.** Chiral anionic ligands for zinc(II). Boc-Pro-O<sup>-</sup>, Boc-Pip-O<sup>-</sup> and TIPSy<sup>-</sup> are derived from *N*-(tert-butoxycarbonyl)-proline, *N*-(tert-butoxycarbonyl)-pipercolonic acid and 3,3'-bis(triphenylsilyl)-1,1'-binaphthyl-2,2'-diyl hydrogenphosphate respectively.

## Results and discussion

## Synthesis

Fluorinated motifs have great utility for both controlling the helical screw-sense in Aib foldamers and reporting on the helical excess of Aib foldamers.<sup>8,27-29</sup> The TFEA <sup>19</sup>F NMR reporter group allows the determination of the helical excess induced at the N-terminus of Aib foldamers (h.e.o.) both in organic solvents, micelles and when embedded in phospholipid vesicles.<sup>25,26</sup> The robustness of TFEA towards synthetic conditions made it attractive for the development of new binding pockets. Either the (*R*)- or the (*S*)-TFEA reporter were conjugated to the readily accessible foldamer  $\text{N}_3(\text{Aib})_4\text{OH}$ , then azide hydrogenation and elaboration at the N-terminus gave key bis-alkyne precursors (*R*)-7 and (*S*)-7 (Scheme 1). CuAAC reactions on these precursors had been shown to give BTPA-capped fluorescent foldamers (*R*)-2 and (*S*)-2.<sup>26</sup> Applying the same CuAAC procedure but using  $\text{N}_3\text{AibO}^t\text{Bu}$ ,<sup>13</sup> 8-azido-3,6-dioxaoctanol or 8-azido-3,6-dioxaoctyl mesylate gave the other *N*-functionalised BTPA foldamers (*S*)-3, (*R*)-4 and (*R*)-8 in good yield (ESI Section 2). Foldamer (*R*)-8 in turn gave access to (*R*)-5, which has a catechol/oligo(ethyleneglycol) bridge that was created through a Cs<sup>+</sup> templated  $\text{S}_\text{N}2$  reaction. This oligoether bridge is close to

the tetrapodal Zn(II) chelating site and might enhance or otherwise alter ligand recognition at Zn(II). It could also permit the introduction of rotaxanated structures.

Installing a monoalkyne in the place of the dialkyne in **7** can give a unsymmetrical metal ion binding sites (Figure 3). The (pyridyl)(triazolyl)(pyridyl)amine (PTPA) moiety of (*R*)-**6** was accessed by reductive amination of amine **9**.<sup>30</sup> Mono-alkyne precursor **10** was hydrolysed then coupled to NH<sub>2</sub>(Aib)<sub>4</sub>((*R*)-TFEA). Finally a CuAAC reaction with N<sub>3</sub>AibO<sup>t</sup>Bu<sup>13</sup> provided PTPA-capped foldamer (*R*)-**6**.

### Addition of zinc(II) perchlorate

Foldamer **2** was chosen to exemplify complexation of Zn(II) by the BTPA group. Foldamer (*R*)-**2** was titrated with zinc perchlorate in CD<sub>3</sub>CN (Figure 5).<sup>31</sup> <sup>1</sup>H NMR spectroscopy showed a gradual, generally downfield, shift of aromatic peaks over the course of the titration, consistent with fast exchange between free and complexed foldamers at substoichiometric ratios of Zn(II). Concurrent resonance broadening was also initially observed, before sharpening and a decrease of chemical shift movement at ca. 0.7 eq. of zinc. After complexation, significant downfield shifts were observed for the *ortho*-pyridyl (H<sub>o</sub>), *para*-pyridyl (H<sub>p</sub>), and triazole (H<sub>t</sub>) proton resonances (Δδ = 187, 428

and 218 ppb respectively, Figure 5 and Figure S1 in the ESI), shifts that are consistent with coordination to Zn(II).<sup>32</sup> Another diagnostic change was a downfield shift (280 ppb) and splitting of the triazole-methylene (H<sub>arm</sub>) protons from a singlet to four doublets (Figure S1 in the ESI), consistent with Zn(II) complexation stopping tertiary amine inversion and making the arms inequivalent with diastereotopic methylenes. <sup>19</sup>F NMR spectroscopy showed that Zn(II) complexation at the N-terminus gave only a very small +8 ppb downfield shift for the C-terminal CF<sub>3</sub> resonance of the reporter group (Figure 5c), indicating little involvement with the newly installed Zn(II). Similar changes were observed for (*S*)-**3**, (*R*)-**4** and (*R*)-**5** (ESI Section 3). However, the <sup>1</sup>H NMR spectrum of Zn((*R*)-**5**)-2ClO<sub>4</sub> (see the ESI, Figure S4) showed an increase in the number and broadness of peaks from the crown-ether protons, suggesting additional conformational states for the macrocycle after Zn(II) addition. Interestingly, the catechol protons were downfield shifted (Δδ ca. 130 ppb, Figure S4) suggesting that the phenyl ring may be bent over the binding pocket. Analysis of model compound Zn(**S21**)-2ClO<sub>4</sub>, which lacks the Aib foldamer, supported this suggestion as it showed a NOE between the catechol protons and a methylene at the other end of the crown ether macrocycle (the OCH<sub>2</sub>CH<sub>2</sub>N protons, Figures S6,7).

(b) Partial stacked <sup>1</sup>H NMR spectra (CD<sub>3</sub>CN, 400 MHz, 298 K). (c) Partial stacked <sup>19</sup>F NMR spectra (CD<sub>3</sub>CN, 376 MHz, 298 K); spectra referenced with C<sub>6</sub>F<sub>6</sub> at -164.38 ppm.<sup>33</sup>

Although the binding pocket of  $\text{Zn}((R)\text{-}6)\text{2ClO}_4$  is less symmetric than the others, analogous behaviour was observed upon addition of zinc(II) perchlorate (Figure S8,9). However, unlike the foldamers with symmetric binding pockets (e.g.  $(R)\text{-}5$ , Figure 6a), the addition of zinc(II) perchlorate to  $(R)\text{-}6$  caused the  $^{19}\text{F}$  singlet to split into two overlapping singlets (Figure 6d,  $\Delta\delta = 29$  ppb). This is consistent with complexation to  $\text{Zn}(\text{II})$  generating a chiral centre at the N-terminus (Figure 6c), which in conjunction with the chiral  $(R)\text{-TFEA}$  group leads to the formation of diastereomeric complexes with distinct  $\text{CF}_3$  resonances. Addition of EDTA to sequester the zinc(II) supported this hypothesis, as the two peaks merged and returned to their original position (Figure S9).

**Figure 6.** (a,b) Complexation of  $\text{Zn}(\text{II})$  to  $(R)\text{-}5$  in  $\text{CD}_3\text{CN}$  gives a small change in  $\delta_F(\text{CF}_3)$  in the  $^{19}\text{F}$  NMR spectrum. (c,d) Complexation of  $\text{Zn}(\text{II})$  to  $(R)\text{-}6$  in  $\text{CD}_3\text{CN}$  causes splitting of the  $\text{CF}_3$  resonance in the  $^{19}\text{F}$  NMR spectrum due to the generation of a stereogenic centre at the N-terminus and the production of diastereomers.

### Complexation studies with anions in $\text{CD}_3\text{CN}$

#### Binding to acetate

As a simple anion for initial binding studies, achiral tetra-*n*-butylammonium (TBA) acetate was used. TBA acetate (up to 2 eq.) was titrated into  $\text{Zn}((R)\text{-}2)\text{2ClO}_4$ . Both  $^1\text{H}$  and  $^{19}\text{F}$  NMR spectroscopy confirmed that acetate bound to the  $\text{Zn}(\text{II})$  pocket. Its enantiomer,  $\text{Zn}((S)\text{-}2)\text{2ClO}_4$ , showed the same changes.

The *ortho*-pyridyl proton ( $\text{H}_o$ ) resonance splits into two. One resonance gradually moves downfield by ca. 0.213 ppm, suggesting the unbound state and this bound state are in fast exchange on the  $^1\text{H}$  NMR spectroscopy timescale. Another  $^1\text{H}$  NMR resonance for  $\text{H}_o$  also appears further downfield (by ca. 1 ppm) after 0.1 eq. ligand has been added; this resonance disappears after 1.4 eq. ligand has been added (Figure 7b). This  $\text{H}_o$  signal seems to come from a new species that is in slow exchange with the other two species. A corresponding new  $^{19}\text{F}$  resonance also appears, upfield of the original reporter signal, mirroring the new signal in the  $^1\text{H}$  NMR spectrum by appearing at 0.1 eq. and disappearing at 1.4 eq. This mirroring indicates that the new signals arise from a single species. Indeed after this new peak has disappeared, the  $^{19}\text{F}$  NMR spectrum showed no shift from the uncomplexed  $^{19}\text{F}$  peak (Figure 7c), confirming that an achiral carboxylate has no effect over the *P/M* ratio. Diffusion ordered spectroscopy (DOSY)  $^1\text{H}$  spectra of  $\text{Zn}((R)\text{-}2)\text{2ClO}_4$  with and without 0.7 eq. of TBA acetate confirmed that these new peaks belong to a single separate species. The DOSY data also shows that this species is larger than uncomplexed  $\text{Zn}((R)\text{-}2)\text{2ClO}_4$ , with a hydrodynamic radius of 13.6 Å compared to 10.2 Å for the acetate-free foldamer (ESI Section 4.3.3.). These DOSY data suggest the new species may involve more than one foldamer.

**Figure 7.** (a) Acetate complexed to  $\text{Zn}((R)\text{-}2)\text{2ClO}_4$ . (b) Partial  $^1\text{H}$  NMR spectra (400 MHz, 298 K) showing the *ortho*-CH resonance during the titration of  $\text{Zn}((R)\text{-}2)\text{2ClO}_4$  (4.25 mM, 550 µL) in  $\text{CD}_3\text{CN}$  with TBA acetate (47 mM, up to 2 eq.). (c) Partial  $^{19}\text{F}$  NMR spectra (376 MHz, 298 K) showing the TFEA reporter region during the titration of  $\text{Zn}((R)\text{-}2)\text{2ClO}_4$  (4.25 mM, 550 µL) in  $\text{CD}_3\text{CN}$  with TBA acetate (47 mM, up to 2 eq.). Spectra referenced with  $\text{C}_6\text{F}_6$  at  $-164.38$  ppm.<sup>33</sup>

## Binding to chiral anions

In previous work, Boc-D-Pro, Boc-D-Pip and S-TiPSY, were all shown to produce an *M* screw-sense in  $\text{Zn}((R)\text{-}2)\text{·}2\text{ClO}_4$  or  $\text{Zn}((S)\text{-}2)\text{·}2\text{ClO}_4$ .<sup>26</sup> The maximum h.e.<sub>0</sub> (the helical excess induced adjacent to the chiral group) of each was estimated by interpolation of  $\Delta\delta_{\text{F}}(\text{CF}_3)$  into our previously reported calibration curve (ESI Section 5),<sup>25,26</sup> giving h.e.<sub>0</sub> values of -21%, -7% and -23% respectively.<sup>34</sup> Although these values are half (or less) of the h.e.<sub>0</sub> values that these ligands induced in  $\text{Zn}(\mathbf{1})\text{·}2\text{ClO}_4$ ,<sup>35</sup> this performance is better than other analogues of  $\text{Zn}(\mathbf{1})\text{·}2\text{ClO}_4$  that had the quinolyl or pyridyl motifs replaced by pyridyl or triazolyl respectively; these gave no clear relays of chirality. Instead complex behaviour was observed, including equilibria with unfavourable exchange kinetics for NMR studies and low solubility.<sup>14,35</sup> To understand how replacing the quinolyl groups with triazolyl avoids these problems, these three chiral anions (Figure 4) were titrated into  $\text{Zn}(\text{BTPA})$ -capped foldamers and the equilibria monitored by  $^1\text{H}$  and  $^{19}\text{F}$  NMR spectroscopy. Both  $\text{Zn}((R)\text{-}2)\text{·}2\text{ClO}_4$  and  $\text{Zn}((S)\text{-}2)\text{·}2\text{ClO}_4$  were titrated with up to 2 eq. Boc-D-Pro or Boc-L-Pro in the presence of 2,6-lutidine (a non-coordinating base, 1.2 eq. with respect to Boc-Pro).<sup>9a</sup> The four combinations give pairs of enantiomeric mixtures, e.g.  $\text{Zn}((R)\text{-}2)\text{·}2\text{ClO}_4/\text{Boc-L-Pro}$  is enantiomeric with  $\text{Zn}((S)\text{-}2)\text{·}2\text{ClO}_4/\text{Boc-D-Pro}$  (Figure 8) and gives identical NMR spectra during the titration.

No significant problems with exchange kinetics or solubility were observed. The  $^1\text{H}$  NMR spectra of  $\text{Zn}((R)\text{-}2)\text{·}2\text{ClO}_4$  showed a downfield shift of the *ortho*-pyridyl ( $\text{H}_o$ ) resonance with Boc-D-Pro and Boc-L-Pro (with 2,6-lutidine, ESI Figure S14). As observed for acetate, this shift was gradual with increasing ligand concentration, which is indicative of fast exchange between the unbound and ligand-bound states on the  $^1\text{H}$  NMR spectroscopy time-scale at 298 K. However, unlike during the addition of TBA acetate, no additional  $\text{H}_o$  signal appeared further downfield in the  $^1\text{H}$  NMR spectrum. Instead the resonance became much weaker and quite broad (albeit still visible) between 0.3 and 1 eq. of Boc-Pro. The  $^1\text{H}$  NMR resonances from the (*R*)-TFEA reporter were little affected by the addition of carboxylate.

In the  $^{19}\text{F}$  NMR spectrum, the titration of up to 2 eq. Boc-D-Pro (with 2,6-lutidine) into  $\text{Zn}((R)\text{-}2)\text{·}2\text{ClO}_4$  gave a gradual downfield shift in  $\delta_{\text{F}}(\text{CF}_3)$ , confirming an increase in the proportion of *M* helix (Figure 8a). Conversely, titration of Boc-D-Pro into the enantiomer  $\text{Zn}((S)\text{-}2)\text{·}2\text{ClO}_4$  gave a gradual upfield shift in  $\delta_{\text{F}}(\text{CF}_3)$ ; this is also consistent with an increase in the proportion of *M* helix (Figure 8b). Plotting  $\Delta\delta_{\text{F}}(\text{CF}_3)$  against concentration revealed a clear sigmoidal profile. Above 2 eq. Boc-D-Pro,  $\delta_{\text{F}}(\text{CF}_3)$  remaining constant. The sigmoidal titration profiles for  $\text{Zn}((R)\text{-}2)\text{·}2\text{ClO}_4$  and  $\text{Zn}((S)\text{-}2)\text{·}2\text{ClO}_4$  are consistent with the formation of intermediates at sub-stoichiometric Boc-Pro that are not visible in the  $^{19}\text{F}$  NMR spectrum.

**Figure 8.** (a) Partial  $^{19}\text{F}$  NMR spectra (376 MHz, 298 K) showing the  $\text{CF}_3$  region during the titration of  $\text{Zn}((R)\text{-}2)\text{·}2\text{ClO}_4$  (4.25 mM, 550  $\mu\text{L}$ ) in  $\text{CD}_3\text{CN}$  with 47 mM Boc-Pro (up to 2 eq. and 2.4 eq. 2,6-lutidine).  $\text{C}_6\text{F}_6$  as an internal standard, referenced at -164.38 ppm.<sup>33</sup> This internal standard gave  $\delta_{\text{F}}(\text{CF}_3)_0$  as -77.6648 ppm. (b) Representative data fitting of  $\Delta\delta_{\text{F}}(\text{CF}_3)$  using Dynafit during the titration of  $\text{Zn}((S)\text{-}2)\text{·}2\text{ClO}_4$  in  $\text{CD}_3\text{CN}$  with Boc-D-Pro. Binding model: 2:1  $[\text{Zn}((S)\text{-}2)\text{·}2\text{ClO}_4]/[\text{Boc-D-Pro}]$  with  $K_{11} = 1 \times 10^5 \text{ M}^{-1}$  and  $K_{21} = 2 \times 10^3 \text{ M}^{-1}$ . Conditions:  $[\text{Zn}((S)\text{-}2)\text{·}2\text{ClO}_4] = 8.36 \text{ mM}$ ,  $[\text{Boc-Pro}] = 0\text{--}18.9 \text{ mM}$ ,  $[2,6\text{-lutidine}] = 0\text{--}22.7 \text{ mM}$ .  $\text{CFCl}_3$  as an internal standard, referenced at -1.14 ppm.<sup>31,33</sup> This internal standard gave  $\delta_{\text{F}}(\text{CF}_3)_0$  as -77.6205 ppm.

Titration with Boc-D-Pip produced similar effects to Boc-D-Pro. Addition of Boc-D-Pip/2,6-lutidine to  $\text{Zn}((R)\text{-}2)\text{·}2\text{ClO}_4$  in  $\text{CD}_3\text{CN}$  resulted in strong broadening of the  $\text{H}_o$  resonance in the  $^1\text{H}$  NMR spectrum with the concurrent appearance of a new, downfield broadened peak at 9.46 ppm (ESI Figure S18). Both  $\text{H}_o$  resonances were very weak between 0.3 and 1.0 equivalents of ligand (ESI Section 4.3.6.) but the observation of two, albeit broadened, resonances during the titration suggests slower exchange on the  $^1\text{H}$  NMR spectroscopy timescale than Boc-Pro. In contrast,  $\delta_{\text{F}}(\text{CF}_3)$  in the  $^{19}\text{F}$  NMR spectrum gradually shifts downfield, consistent with fast exchange between free and bound foldamer.  $\delta_{\text{F}}(\text{CF}_3)$  follows a sigmoidal profile during the

titration but with extensive signal broadening between 0.4 and 1 eq. Boc-D-Pip (ESI Figure S19).

**Figure 9:** Partial  $^{19}\text{F}$  NMR spectra (376 MHz, 298 K) showing the  $\text{CF}_3$  region for the titration of  $\text{Zn}((R)\text{-}2)\cdot 2\text{ClO}_4$  (4.25 mM, 550  $\mu\text{L}$ ) in  $\text{CD}_3\text{CN}$  with 47 mM TiPSY (up to 2 eq. and 2.4 eq. 2,6-lutidine).  $\text{C}_6\text{F}_6$  as an internal standard, referenced at  $-164.38$  ppm.<sup>33</sup>

Like carboxylates, phosphates are reported to complex to zinc-tetraamine complexes,<sup>36–38</sup> so the chiral TiPSY anion was also assessed (Figure 4). TiPSY/2,6-lutidine however produced different behaviour upon titration into  $\text{Zn}((R)\text{-}2)\cdot 2\text{ClO}_4$ . The  $^1\text{H}$  and  $^{19}\text{F}$  NMR spectra show the bound and unbound states are now in slow exchange (Figure 9 and ESI Figures S20–22), with integration of the signals providing no evidence for the formation of an intermediate species during the addition of TiPSY/2,6-lutidine. The TiPSY anion is a much larger ligand than acetate, Boc-Pro- $\text{O}^-$  or BocPip- $\text{O}^-$ , perhaps creating a steric block to the formation of intermediate complexes that involve more than one foldamer.

Changing from the flat aromatic moieties in  $\text{Zn}((S)\text{-}2)\cdot 2\text{ClO}_4$  to the 2-isobutyrate of  $\text{Zn}((S)\text{-}3)\cdot 2\text{ClO}_4$  was hoped to encumber the binding site and allow bound ligands to better control helical screw-sense. Adding Boc-D-Pro/2,6-lutidine to  $\text{Zn}((S)\text{-}3)\cdot 2\text{ClO}_4$  induced an *M*-helical bias, the same as for  $\text{Zn}((S)\text{-}2)\cdot 2\text{ClO}_4$  (ESI Figure S24). Indeed the induction of *M* helix by Boc-D-Pro- $\text{O}^-$  (and vice versa for Boc-L-Pro- $\text{O}^-$ ) was observed for all BTPA-capped Aib foldamers tested (ESI Section 5), which is the same screw-sense induced in BQPA-capped Aib foldamers by Boc-D-Pro- $\text{O}^-$ .<sup>9a,14,15,39</sup> The kinetics of exchange in this complex are slower and more comparable to Boc-Pip with  $\text{Zn}((S)\text{-}2)\cdot 2\text{ClO}_4$ . For  $\text{Zn}((S)\text{-}3)\cdot 2\text{ClO}_4$ , interpolating the induced chemical shifts for Boc-D-Pro ( $-81$  ppb;  $+76$  ppb for Boc-L-Pro) into the calibration curve showed the h.e.<sub>0</sub> (32%) is greater than for  $\text{Zn}((S)\text{-}2)\cdot 2\text{ClO}_4$  (21%, see Table 1).

**Table 1.** Calculated helical excess (h.e.<sub>0</sub>) values induced by excess Boc-Pro/2,6-lutidine ( $\geq 2$  eq.) for  $\text{Zn}(\mathbf{2-6})\cdot 2\text{ClO}_4$ . Values calculated from shifts of resonances ( $\Delta\delta_{\text{F}}(\text{CF}_3)$ ) in the  $^{19}\text{F}$  NMR spectra (downfield for  $\text{Zn}((S)\text{-}3)\cdot 2\text{ClO}_4$ , upfield for the others).

Foldamer	h.e. <sub>0</sub> <sup>a</sup>
$\text{Zn}((R)\text{-}2)\cdot 2\text{ClO}_4$	+21% (with Boc-L-Pro)
$\text{Zn}((S)\text{-}3)\cdot 2\text{ClO}_4$	+32% (with Boc-L-Pro) <sup>b</sup>
$\text{Zn}((R)\text{-}4)\cdot 2\text{ClO}_4$	+29% (with Boc-L-Pro)
$\text{Zn}((R)\text{-}5)\cdot 2\text{ClO}_4$	+29% (with Boc-L-Pro)
$\text{Zn}((R)\text{-}6)\cdot 2\text{ClO}_4$	+21% (with Boc-L-Pro)

<sup>a</sup> h.e.<sub>0</sub> values are estimated from  $\Delta\delta_{\text{F}}(\text{CF}_3)$  values according to a nonlinear model<sup>25</sup> (ESI Section 5). <sup>b</sup> The spectroscopic changes are reversed but Boc-L-Pro still induces *P* helix.

Very similar behaviour was observed for the titration of  $\text{Zn}((R)\text{-}4)\cdot 2\text{ClO}_4$  and  $\text{Zn}((R)\text{-}5)\cdot 2\text{ClO}_4$  with Boc-Pro (either D or L) under analogous experimental conditions (ESI Sections 4.5 and 4.6 respectively). Both showed fast exchange between bound and unbound foldamer and both gave h.e.<sub>0</sub> values of +29% after addition of 2 eq. Boc-L-Pro/2,6-lutidine (Table 1). As observed for  $\text{Zn}(\mathbf{1})\cdot 2\text{ClO}_4$ ,<sup>15</sup> fast carboxylate exchange at zinc(II) on the NMR spectroscopy timescale was confirmed and the non-coordinating base 2,6-lutidine only bound weakly (ESI Figure S35). The former was confirmed by using different scalemic mixtures of Boc-Pro;  $\delta_{\text{F}}(\text{CF}_3)$  correlated with the ee of the mixtures (Figure S37). Notably, addition of a 1:1 mixture of Boc-(D/L)-Pro to  $\text{Zn}((R)\text{-}4)\cdot 2\text{ClO}_4$  gave  $\delta_{\text{F}}(\text{CF}_3)$  at the same position, within the experimental error, as that of uncomplexed  $\text{Zn}((R)\text{-}4)\cdot 2\text{ClO}_4$  (i.e. h.e.<sub>0</sub> = 0 in both cases).

As expected, given that it exists as two diastereomers, titration of unsymmetrical  $\text{Zn}((R)\text{-}6)\cdot 2\text{ClO}_4$  with Boc-Pro (either D- or L-) gave complex data with multiple  $\text{CF}_3$  resonances observed (ESI Section 4.7). Nonetheless these changes were broadly similar to those observed with symmetric  $\text{Zn}((R)\text{-}4)\cdot 2\text{ClO}_4$ .

#### Binding model and estimation of carboxylate affinity for $\text{Zn}(\mathbf{2-5})\cdot 2\text{ClO}_4$ in $\text{CD}_3\text{CN}$

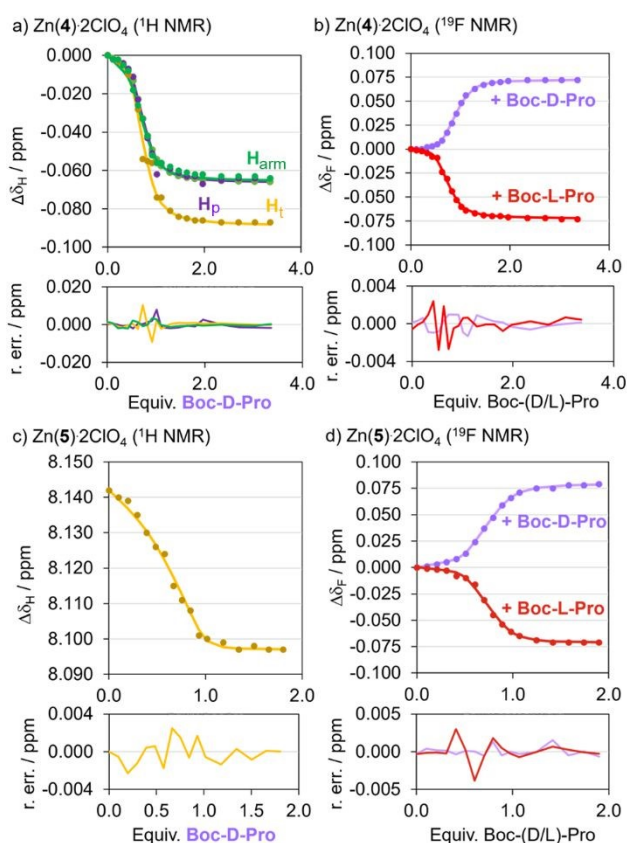

The equilibria between different Boc-Pro/foldamer complexes were modelled. The sigmoidal profiles in the  $^1\text{H}$  NMR and  $^{19}\text{F}$  NMR data during titrations with Boc-Pro or Boc-Pip are similar to that observed during the TBA acetate titration of  $\text{Zn}((R)\text{-}2)\cdot 2\text{ClO}_4$  and suggest that an intermediate is formed. This is presumed to be a 2:1 foldamer:ligand complex. We believe that because of the exchange kinetics when Boc-Pro/Boc-Pip (with 2,6-lutidine) are used as titrants, this intermediate species is not observable by NMR spectroscopy for these anions. The structure of this intermediate 2:1 complex is unknown but we speculate that the carboxylate is bridging between zinc centres, which has been reported for similar complexes.<sup>40</sup> This may be a coordination mode permitted by the relatively open face of the BTPA binding pocket compared to the encumbered BQPA binding pocket of  $\text{Zn}(\mathbf{1})\cdot 2\text{ClO}_4$ . This bridged species may be disfavoured for the large bulky TiPSY anion.

In order to estimate the affinity of Boc-Pro for the  $\text{Zn}(\text{BTPA})$ -capped foldamers, we used SupraFit and Dynafit to calculate

the binding constants (Figures 8b and 10, also see the ESI).<sup>41,42</sup> We used a 2:1 foldamer:anion binding model for data fitting, with the binding constant  $K_{11}$  representing the formation of the 1:1 complex and the binding constant  $K_{21}$  representing the formation of the intermediate 2:1 complex from the 1:1 complex and another equivalent of foldamer. Since for acetate binding, uncomplexed  $\text{Zn}((R)\text{-4})\cdot 2\text{ClO}_4$  and the 1:1 complex are in fast exchange with each other but the 2:1 complex is not, we assume the 2:1 complex should not affect the chemical shift of the 1:1 complex and fitting of the latter's chemical shift data should give an estimate of both binding constants. Nonetheless fitting the data to two equilibria presents challenges, with small uncertainties in concentration leading to significant differences in the individual binding constants  $K_{11}$  and  $K_{21}$ .

**Figure 10.** Representative data fitting with Suprafit.<sup>41</sup> For fits, see the ESI (Sections 4.5 and 4.6). (a) Global fit of  $^1\text{H}$  protons of  $\text{Zn}((R)\text{-4})\cdot 2\text{ClO}_4$  titrated with Boc-D-Pro. (b) Fits of the  $^{19}\text{F}$  peak of  $\text{Zn}((R)\text{-4})\cdot 2\text{ClO}_4$  titrated with Boc-D-Pro (purple) or Boc-L-Pro (red). (c) Fit of the triazole proton of  $\text{Zn}((R)\text{-5})\cdot 2\text{ClO}_4$  ( $\text{H}_l$ ) titrated with Boc-D-Pro. (d) Fits of the  $^{19}\text{F}$  peak of  $\text{Zn}((R)\text{-5})\cdot 2\text{ClO}_4$  titrated with Boc-D-Pro (blue) or Boc-L-Pro (red). Binding model: 2:1 [foldamer]/[anion] (See Eqns 1,2 in ESI Section 4.2). Conditions:  $[\text{Zn}((R)\text{-4})\cdot 2\text{ClO}_4] = 2 \text{ mM}$ ,  $[\text{Boc-Pro}] = 0\text{--}6.7 \text{ mM}$ ,  $[\text{2,6-lutidine}] = 0\text{--}7.2 \text{ mM}$ .  $[\text{Zn}((R)\text{-5})\cdot 2\text{ClO}_4] = 2 \text{ mM}$ ,  $[\text{Boc-Pro}] = 0\text{--}3.6 \text{ mM}$ ,  $[\text{2,6-lutidine}] = 0\text{--}4.3 \text{ mM}$ .  $^{19}\text{F}$  NMR spectra referenced with  $\text{C}_6\text{F}_6$  at  $-164.38 \text{ ppm}$ .<sup>31,33</sup> R. err.: residual error (in ppm).

The titration of  $\text{Zn}((S)\text{-2})\cdot 2\text{ClO}_4$  with Boc-D-Pro gave  $^{19}\text{F}$  NMR data (Figure 8b) and  $^1\text{H}$  data (ESI Figure S16) that fitted a 2:1 binding model adequately using  $K_{11} = 1 \times 10^5 \text{ M}^{-1}$  and  $K_{21} = 2 \times 10^3 \text{ M}^{-1}$ . The titration of foldamers  $\text{Zn}((R)\text{-4})\cdot 2\text{ClO}_4$  and  $\text{Zn}((R)\text{-5})\cdot 2\text{ClO}_4$  with both Boc-L-Pro and Boc-D-Pro could also be adequately fitted to a 2:1 binding model (Figure 10). Within the uncertainty associated with fitting the formation of multiple

complexes, there is reasonable agreement (within an order of magnitude) between the binding constants calculated for foldamers  $\text{Zn}((R)\text{-4})\cdot 2\text{ClO}_4$  and  $\text{Zn}((R)\text{-5})\cdot 2\text{ClO}_4$  (approximate values:  $K_{11} = 1$  to  $4 \times 10^6 \text{ M}^{-1}$  and  $K_{21} = 1$  to  $2 \times 10^4 \text{ M}^{-1}$ ); these are an order of magnitude higher than the analogous values for  $\text{Zn}((S)\text{-2})\cdot 2\text{ClO}_4$ . These values for  $K_{11}$  ( $\text{ca. } \sim 10^6 \text{ M}^{-1}$ ) are similar to  $K_{11}$  for the complexation of Boc-Pro to  $\text{Zn}(\text{1})\cdot 2\text{ClO}_4$  ( $4 \times 10^6 \text{ M}^{-1}$ ) in  $\text{CD}_3\text{CN}$ , although in that case there was no indication of an intermediate complex.<sup>35</sup> The  $K_{21}$  binding constants ( $\text{ca. } 10^4 \text{ M}^{-1}$ ) are approximately 100-fold smaller than  $K_{11}$ , which is consistent with a steric barrier inhibiting the formation of this 2:1 complex. The similarity of the Boc-Pro binding constants for  $\text{Zn}((R)\text{-4})\cdot 2\text{ClO}_4$  and  $\text{Zn}((R)\text{-5})\cdot 2\text{ClO}_4$  indicate changing the oligoethyleneglycol for a crown ether has little influence on the binding of carboxylates. Estimated  $K$  values for  $\text{Zn}((R)\text{-4-6})\cdot 2\text{ClO}_4$  are summarised in Tables S1-S5 (see the ESI).

## Conclusions

The modular nature of CuAAC allows the construction of bis(triazole)pyridyl (BTPA) metal ion chelation sites that are flanked by different substituents, e.g. by a fluorophore or a crown ether bridge. Carboxylate and phosphate ligands both bind tightly to the  $\text{Zn}(\text{BTPA})$  group, with the  $\text{Zn}(\text{BTPA})$  structure allowing bound ligands to induce local conformational changes in the adjacent  $3_{10}$  helical Aib foldamer body. Corresponding increases in the proportion of either the *P* or the *M* screw-sense were detected by  $^{19}\text{F}$  NMR spectroscopy using the recently developed 1-(trifluoromethyl)-ethylamido (TFEA) reporter group.<sup>25</sup>

The strength of helical induction by different ligands was lower than that reported for the same ligands when bound to a previously described bis(quinolyl)pyridyl (BQPA)-capped foldamer. The greater hindrance created by the quinolyl arms compared to the more open face presented by the triazoles in  $\text{Zn}(\text{BTPA})$  complexes is proposed to lead to the better performance of BQPA. Lower steric encumbrance around the  $\text{Zn}(\text{BTPA})$  site is also proposed to permit additional coordination equilibria, with new intermediates observed at substoichiometric carboxylate that are not found with  $\text{Zn}(\text{BQPA})$  foldamers. DOSY and titration data suggest these intermediates are  $(\text{foldamer})_2(\text{carboxylate})$  complexes.

Nonetheless, the new BTPA binding site does not suffer from the drawbacks observed in previous replacements for BQPA.<sup>14</sup> Despite showing similar coordination geometries to  $\text{Zn}(\text{1})\cdot 2\text{ClO}_4$ , either replacing the quinolyl arms with pyridyl arms or replacing the pyridyl link with a triazolyl link led to foldamers with undesirable characteristics, including poor solubility, unfavourable ligand exchange rates on the NMR timescale, and inefficient relays of conformational information from the bound carboxylate (i.e. Boc-Pro). In contrast, all tested  $\text{Zn}(\text{BTPA})$ -capped foldamers were soluble, had clear resonances at room temperature and possessed an effective conformational relay. These properties show that the modular BTPA motif is a versatile alternative to BQPA.

The versatility of CuAAC chemistry also permitted the creation of an unsymmetrical binding site on an Aib foldamer. The

unsymmetrical binding site generated a chirogenic centre at the N-terminus upon Zn(II) complexation. The conformational preference of each handedness of the chirogenic Zn(II) complex is relayed along the foldamer body to the chiral CF<sub>3</sub> containing reporter group, leading to different <sup>19</sup>F NMR spectroscopic outputs from each diastereomer. The net effect is to allow an achiral messenger (Zn(II)) to produce a spectroscopic output from the remote chiral TFEA reporter group.

With the Zn(BTPA) ligand binding site shown to mediate ligand-induced conformational change, the modular assembly of functional binding sites by CuAAC should lend itself to the generation of more complex constructs that better mimic natural binding sites in proteins. In this way ligand-triggered conformational change in larger and more functional foldamers will become possible.

## Author contributions

S.J.W. conceived the idea, acquired the funding, administered the project. F.D.S. B.D. and S.J.W. designed the experiments, analysed the data and wrote the manuscript. F.D.S. and B.D. and carried out the experimental work. S.J.W. provided resources and supervision.
