A CH₂Cl₂ complex of a [Rh(pincer)]⁺ cation†

Gemma M. Adams, F. Mark Chadwick, Sebastian D. Pike and Andrew S. Weller*

The CH₂Cl₂ complex [Rh(^tBuPONOP)(κ¹-ClCH₂Cl)][BAR^F₄] is reported, that also acts as a useful synthon for other complexes such as N₂, CO and H₂ adducts; while the analogous PNP complex undergoes C–Cl activation.

Coordinatively and electronically unsaturated transition-metal pincer complexes, [M(pincer)], are key intermediates in alkane dehydrogenation processes,¹ as well as other catalytic transformations.² They have also played a major role in the elucidation of fundamental bond transformations, such as C–H, C–C and C–X breaking and making.³ Recently, Brookhart and co-workers reported the synthesis of transition-metal methane and ethane sigma complexes, by a low temperature (*ca.* –110 °C to –150 °C) protonation of the corresponding Rh(^tBuPONOP)R precursors using [H(OEt)₂][BAR^F₄] in CDF₂Cl–CH₂Cl₂ solvent to give [Rh(^tBuPONOP)(H–R)][BAR^F₄] [^tBuPONOP = 2,6-(^tBu₂PO)₂C₅H₃N; R = Me, Et; Ar^F = 3,5-(CF₃)₂C₆H₃], Scheme 1.⁴ Such complexes are key, but transient, intermediates in C–H bond activation processes. On warming above –87 °C (R = Me) or –130 °C (R = Et) they lose alkane and generate complexes tentatively characterised *in situ* on the basis of ³¹P NMR spectroscopy as [Rh(^tBuPONOP)(solv)][BAR^F₄] (solv = CDF₂Cl or CD₂Cl₂). These solvent adducts remain to be definitively characterised. They are particularly interesting given their role in alkane coordination chemistry, and more generally as latent-low coordinate intermediates in catalytic processes.

We now report the full characterisation of the CH₂Cl₂ adduct accessed *via* a different, halide abstraction, route including a single crystal X-ray diffraction study and its onward reactivity. We also demonstrate that changing the pincer ligand to the more electron donating ^tBuPNP [2,6-(^tBu₂PCH₂)₂C₅H₃N] results in C–Cl bond activation of the solvent molecule.

Scheme 1 Formation of a sigma alkane complex and decomposition to give tentatively characterised solvent complexes (Brookhart and co-workers). [BAR^F₄][–] anions are not shown.⁴

Addition of Na[BAR^F₄] to a CH₂Cl₂ solution of Rh(^tBuPONOP)Cl, **1**,^{4a} results in the formation of orange [Rh(^tBuPONOP)(κ¹-ClCH₂Cl)][BAR^F₄], **2** (Scheme 2). Filtration and removal of the solvent affords **2** in good isolated yield as a powder. Complex **2** can be recrystallised from CH₂Cl₂–pentane under an Ar atmosphere to give crystals suitable for an X-ray diffraction study. Under these conditions, orange **2** crystallises alongside the dinitrogen adduct, [Rh(^tBuPONOP)(κ¹-N₂)][BAR^F₄], **3**, in an approximate 1 : 1 ratio (as measured by ³¹P NMR spectroscopy, *vide infra*). Single crystals of **2** suitable for an X-ray diffraction study were obtained by mechanical separation from orange/brown **3**.[‡] Presumably the exogenous N₂ comes from trace (1–2 ppm) levels of N₂ present in the argon, as has been noted previously,⁵ and is driven by relative solubilities of

Scheme 2 Synthesis of complex **2**. [BAR^F₄][–] anion is not shown.

Complex 5 co-crystallises with $[\text{Rh}(\text{tBuPNP})(\text{H})\text{Cl}][\text{BAR}^{\text{F}}_4]$, **6**, at the same lattice position in a 50 : 50 ratio.†

2 and **3**; as in neat CD_2Cl_2 under the same Ar atmosphere **2** does not go on to form **3** to the detection limit of $^{31}\text{P}\{^1\text{H}\}$ NMR spectroscopy. The solid-state structure (Fig. 1A) shows a pseudo square planar cationic $[\text{Rh}(\text{tBuPONOP})]^+$ centre coordinated in the fourth position by a CH_2Cl_2 molecule. The Rh–Cl1 distance [2.350(2) Å] is significantly shorter than reported for related $[\text{RhCp}^*(\text{PMe}_3)(\text{Ph})(\kappa^1\text{-ClCH}_2\text{Cl})][\text{BAR}^{\text{F}}_4]$, 2.512(2) Å, and $[\text{RhCp}^*(\text{PMe}_3)(\text{Me})(\kappa^1\text{-ClCH}_2\text{Cl})][\text{BAR}^{\text{F}}_4]$, 2.488(1) Å $\text{Cp}^* = \eta^5\text{-C}_5\text{Me}_5$.⁷ Complex **2** adds to the relatively small number of CH_2Cl_2 complexes that have been crystallographically characterised, and in particular CH_2Cl_2 adducts of pincer, or closely related, complexes.⁸

Although the short Rh–Cl distance might suggest a stronger interaction in **2**, in solution (*vide infra*) rapid exchange between solvent and bound CH_2Cl_2 occurs. The two C–Cl distances in the bound solvent molecule are similar, 1.710(8) [C22–Cl1] and 1.758(7) [C22–Cl2] Å, although the distal C–Cl bond is the slightly longer of the two. This is in contrast to other reported CH_2Cl_2 complexes in which the bound C–Cl bond is longer.^{8,9} We suggest that the slight lengthening of C22–Cl2 may be due to a number of weak C–H⋯Cl hydrogen bonds between proximal ^tBu groups and Cl2.¹⁰

Complex **2** is stable in the solid-state under an Ar atmosphere, and in solution (CD_2Cl_2) for at least 1 week. In the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum (CD_2Cl_2) a single resonance is observed at δ 204.5 [$J(\text{RhP})$ 136 Hz]. These data are identical to those previously reported by Brookhart and co-workers for the complex tentatively characterised as $[\text{Rh}(\text{tBuPONOP})(\text{CH}_2\text{Cl}_2)][\text{BAR}^{\text{F}}_4]$, *i.e.* **2**. The ^tBu groups are observed as a single environment in the ^1H NMR spectrum. The bound CH_2Cl_2 ligand is not observed, even at -80°C in the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum, presumably as it is undergoing fast exchange with the solvent.¹¹ The electrospray ionisation mass spectrum of **2** using N_2 as a desorption gas showed only **3** as the molecular ion.

Complex **2** is a useful synthon for the preparation of other pincer complexes (Scheme 3). Addition of H_2 to a CD_2Cl_2 solution of **2** forms the previously reported dihydrogen complex $[\text{Rh}(\text{tBuPONOP})(\eta^2\text{-H}_2)][\text{BAR}^{\text{F}}_4]$ ¹² [$\delta(^1\text{H})$ -8.27 , lit. -8.26]. Addition of N_2 forms the new complex $[\text{Rh}(\text{tBuPONOP})(\kappa^1\text{-N}_2)]$ –

Scheme 3 Reactivity of complex **2**. CH_2Cl_2 solvent. $[\text{BAR}^{\text{F}}_4]^-$ anions are not shown.

$[\text{BAR}^{\text{F}}_4]$, **3**, for which a solid-state structure is shown in Fig. 1B. This demonstrates an end-on bound, monomeric, N_2 adduct [N–N, 1.063(5); Rh–N2, 1.967(3) Å]. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum displays a single environment at δ 211.0 [$J(\text{RhP})$ 132 Hz], while in the IR spectrum the N–N stretch is observed at 2201.9 cm^{-1} . The N–N bond length is very similar (albeit a little shorter) than that in free N_2 [1.09 Å], suggesting only a small degree of activation. Complex **3** can also be compared with previously reported $[\text{Rh}(\text{tBuPNP})(\kappa^1\text{-N}_2)][\text{OTf}]$ which shows a slightly longer N–N bond, a shorter Rh–N bond and a more red-shifted N–N stretch: 1.116(4), 1.898(3) Å, and 2153 cm^{-1} respectively; suggesting greater N_2 activation for this more electron rich pincer ligand.¹³ This greater metal-based basicity in the ^tBuPNP complexes is reflected in the CO stretching frequencies of the corresponding CO-adducts: $[\text{Rh}(\text{tBuPONOP})(\text{CO})][\text{BAR}^{\text{F}}_4]$, **4** [2020 cm^{-1}] and $[\text{Rh}(\text{tBuPNP})(\text{CO})][\text{BAR}^{\text{F}}_4]$ [1982 cm^{-1}].¹⁴ Complex **4** was prepared by adding CO to a CH_2Cl_2 solution of **2**, further demonstrating the utility of complex **2** in synthesis.

The difference in electron-donating power of the ^tBuPONOP versus ^tBuPNP ligands can also be shown by the attempted synthesis of the CH_2Cl_2 adduct of the $[\text{Rh}(\text{tBuPNP})]^+$ fragment, analogous to complex **2**. Rather than simple coordination, this resulted in a number of products as measured by $^{31}\text{P}\{^1\text{H}\}$ NMR spectroscopy. Analysis of single crystals suitable for an X-ray

Scheme 4 Reactivity of $\text{Rh}(\text{tBuPNP})\text{Cl}^{15}$ with $\text{Na}[\text{BarF}_4]$. CH_2Cl_2 solvent. $[\text{BarF}_4]^-$ anions are not shown.

diffraction study, obtained from recrystallisation of the reaction mixture, demonstrated co-crystallisation of two complexes $[\text{Rh}(\text{tBuPNP})(\text{CH}_2\text{Cl})\text{Cl}][\text{BarF}_4]$, **5**, and $[\text{Rh}(\text{tBuPNP})(\text{H})\text{Cl}][\text{BarF}_4]$, **6**, in an approximate 50:50 ratio (Scheme 4); for which the solid-state structure of **5** is shown in Fig. 1C. Because of this co-crystallisation the metrical data associated with **5** should be treated with caution. The ^1H NMR spectrum of these crystals showed a broad hydride signal at $\delta -15.48$ (relative integral relative to $[\text{BarF}_4]$ of ~ 0.5 H) which is assigned to **6**. Given the number of products formed we are reluctant to speculate on mechanism of formation of **6**, but protonation of **5** by trace acid arising from other decomposition pathways could form **6**. Addition of H_2 to this mixture of **5** and **6** in CD_2Cl_2 afforded mixture of products, from which $[\text{Rh}(\text{tBuPNP})(\eta^2\text{-H}_2)][\text{BarF}_4]$ could be identified as the major species present.¹⁶

Conclusions

The CH_2Cl_2 complex $[\text{Rh}(\text{tBuPONOP})(\kappa^1\text{-ClCH}_2\text{Cl})][\text{BarF}_4]$ has been isolated, confirming its formation in the decomposition of the corresponding alkane adduct at low temperature, itself formed from protonation of an alkyl precursor.⁴ Synthesis has been achieved by an alternative halide-abstraction route in CH_2Cl_2 solvent, starting from a readily available chloride precursor. This complex, with its weakly bound CH_2Cl_2 ligand, also acts as a useful synthon for other complexes such as N_2 , CO and H_2 adducts. The corresponding PNP ligand complex undergoes C–Cl activation to form a mixture of products, highlighting the difference in electron donating properties of these two ligands.
