Comprehensive coordination chemistry of iminophosphonamides

Bhupendra Goswami ^a and Peter W. Roesky ^{b,c}

The iminophosphonamide $[R_2P(NR')_2]^-$ ligand is an analog of phosphate ($R_2PO_2^-$), replacing its oxygen atoms with two amide groups. This review aims to provide the first comprehensive report on coordination chemistry dealing with iminophosphonamide ligands, focusing on the s-block, p-block, transition, and f-block metals. In particular, this monoanionic ligand's coordination mode and reactivity with the metal centers are discussed. The last section of the review is dedicated to the reported chiral iminophosphonamine ligands and corresponding metal complexes.

1 Introduction

In coordination chemistry, tailor-made ligand systems are crucial for creating metal complexes with specific properties.¹ Monoanionic chelating ligands such as β -diketiminates,² aminotroponimides,³ bis(phosphinimino)methanides,^{4,5}

Bhupendra Goswami

Bhupendra Goswami obtained his integrated BS-MS dual degree from the Indian Institute of Science Education and Research (IISER) Mohali, India, in 2017. He joined as a doctoral student at the Karlsruhe Institute of Technology, Germany, under the supervision of Prof. Peter W. Roesky and was awarded Dr rer. nat. in 2020. Dr Goswami worked as a postdoc researcher with Prof. Dominik Munz at the University of Saarland, Germany (2021–2022). Subsequently, he joined the Central University of Rajasthan, as an Assistant Professor at the Department of Chemistry in 2022. His current area of research is synthetic inorganic chemistry, coordination chemistry of transition metals and their photoluminescence.

Peter W. Roesky

Peter W. Roesky obtained his diploma in 1992 from the University of Würzburg and his doctoral degree from the Technical University of Munich (with Prof. W. A. Herrmann) in 1994. He was a postdoc with Prof. T. J. Marks at Northwestern University (1995–1996). In 1999 he completed his Habilitation at the University of Karlsruhe. As a Full Professor, he joined the faculty of the Freie Universität Berlin in 2001. In 2008, he became a Full Professor of inorganic functional materials at the Karlsruhe Institute of Technology (KIT). From 2013 to 2015, he served as Dean of the Faculty of Chemistry and Biosciences at KIT. In 2019, he received a JSPS Invitational Fellowship for Research in Japan and in 2020, a Reinhart Koselleck Project of the German Science Foundation. In 2022, he was given the Frank H. Spedding Award for research in Rare Earth Science and in 2024, the Marianne-Baudler-Award of the German Chemical Society (GDCh). Currently, he is the chair of the Wöhler Association for Inorganic Chemistry of the GDCh. His current research interest revolves around the synthetic inorganic and organometallic chemistry of s-block metals, silicon, group 15, gold, and lanthanides.

amidinates,^{6–8} and closely related guanidines^{8–12} are a well-established class of ligand systems. Of these N-donor ligands, amidinates belong to the NXN ligand framework with a carbon atom at the center (*i.e.*, X = C). The coordinated complexes containing an NXN motif are typically referred to as non-metallocene derivatives. Upon replacing the central atom X, many N–X–N-type bidentate chelating ligands can be created, and such ligands are thought of as hetero analogs of the allylic ligand.

The boraamidinate, sulfinamidinate, triazenide, and iminophosphonamide systems are examples of N–X–N ligands, where X = BR,^{13,14} SR,^{15–18} N,^{19,20–23} and PR₂,^{24–26} respectively (Fig. 1). As expected, electronic tuning of the ligand backbone occurs upon alteration of the central atom X in the NXN ligand. It is reasonable to assume that these heteroatomic ligand systems have a similar coordination chemistry. Nonetheless, the ligand system's closure inspection indicates that the corresponding bond lengths and bite angles vary, which significantly affects how the corresponding complexes behave chemically. In contrast to the other NXN ligands, the iminophosphonamides (X = PR₂) have the longest X–N bond (1.60 Å), which result into a comparatively wider bite angle in their metal complexes.²⁶ Furthermore, it has been experimentally observed that some iminophosphonamides can exist in a zwitterionic form, denoted as N[–]–P⁺–N[–], where the negative charge is localized on the nitrogen atoms of the iminophosphonamide ligand. This zwitterionic form is a key difference in the electronic properties between iminophosphonamides and closely related amidinates.²⁷

Additionally, the highest occupied molecular orbital (HOMO) of iminophosphonamide ligands can exhibit either C_{2v} or C_s symmetry, whereas the HOMO of amidinate ligands demonstrates only C_{2v} symmetry. The presence of C_s symmetry in iminophosphonamide ligands allows for effective in-plane donation of π -electron density from the nitrogen center to the d_{xz} orbital of the metal center. In contrast, the C_{2v} symmetric HOMO of amidinates results in only lateral donation, leading to significant puckering of the metallacycles.²⁷

Furthermore, the presence of a phosphorus center in the ligand backbone makes it easy to track the reaction progress *via* ³¹P NMR spectroscopy. Moreover, the central R₂P unit of

the iminophosphonamide offers a higher steric demand in comparison to the other NXN ligand frameworks. By changing the substituents (R, R') in the iminophosphonamide ligand, the steric factor can be varied.

The following three types of bonding modes can be offered by the iminophosphonamide ligand, which depends upon the type of the metal atoms (Fig. 2).

Generally, the following two major preparative approaches can be used to synthesize the iminophosphonamide ligand (Scheme 1):

(1) Kirsanov condensation: in this approach, a bromo phosphonium salt, [R₂PXX']⁺Br[–] (X and X' = Cl or Br), is generated by oxidizing tertiary phosphine, R₂PX (X = Cl and Br) with bromine. In the second step, the produced bromo phosphonium salt can react with primary amines (R'NH₂) to form a diamino phosphonium salt, which is then transformed into the equivalent iminophosphonamine with the aid of a strong base.^{28,29}

(2) Staudinger reaction: the Staudinger reaction for the synthesis of iminophosphonamine is more versatile. In this preparative approach, a reaction is carried out between a stoichiometric quantity of an organic azide (R'N₃) and phosphonamine (R₂PNHR') or phosphine (R₂PH), which immediately releases N₂ and yields the iminophosphonamine ligand.^{30–32}

To avoid any potential hazards associated with the di-substituted phosphanes and azides in the Staudinger reaction, Kirsanov condensation could be employed as an alternative synthetic method.

Based on the above-mentioned synthetic methods, various iminophosphonamine ligands have been reported in the literature. Using these ligands, the literature presents a variety of iminophosphonamide metal complexes, ranging from main group, over transition metals to rare earth metals. The synthesized metal complexes can be formed either by direct deprotonation (Scheme 2a) or through salt metathesis reactions (Scheme 2b).

Scheme 2 Common chemical reactions involved in the synthesis of iminophosphonamide metal complexes, by (a) direct deprotonation or (b) through salt metathesis reactions.

To the best of our knowledge, reviews dealing with the coordination chemistry of most of the above-mentioned NXN ligand systems are known with the exception of iminophosphonamide ligands (Fig. 1).^{13,34–36} Some parts of the review have already been published in the dissertation of one of the authors.³⁷ This review will give a comprehensive account of the coordination chemistry dealing with the iminophosphonamide ligand, particularly coordination modes and reactivity with the s-block, p-block, transition, and rare earth metal elements. This also includes the developments in the field of enantiopure iminophosphonamine ligands so far.

2. Achiral complexes of iminophosphonamides

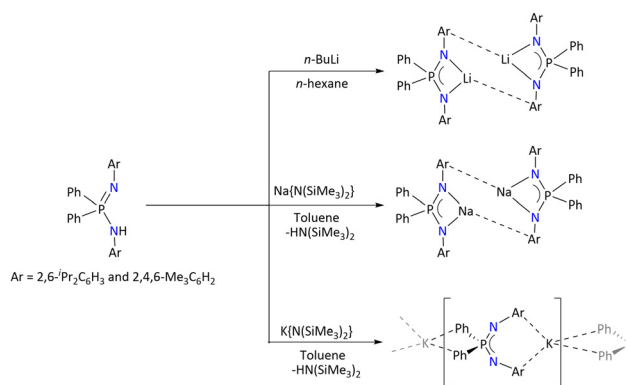

2.1 s-Block metal complexes

The s-block metal complexes of the iminophosphonamine ligand are important since these metal complexes serve as reagents to transfer the ligand to other metal centers.

The alkali metal complexes of the ligand are commonly synthesized by deprotonation of the iminophosphonamines with alkali metal precursors such as *n*-BuLi, NaH, [Na{N(SiMe₃)₂}], KH, [K{N(SiMe₃)₂}], [Rb{N(SiMe₃)₂}], and [Cs{N(SiMe₃)₂}] or direct deprotonation of elemental metals such as rubidium and caesium. The literature represents alkali metal complexes of various NPN motifs such as {Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}H, {Ph₂P(2,4,6-Me₃C₆H₂N)₂}H,^{38,39} {Ph₂P(2,6-*i*-Pr₂C₆H₃NH)P(Ph₂)(=N(C₆H₂-2,4,6-Me₃))},⁴⁰ and {Ph₂PN(SiMe₃)₂}H.⁴¹

Upon closely looking at the structures of alkali metal complexes of the various ligands, it is observed that depending on the ionic radius of the metals and *N*-substituents, the aggregation state of the complexes differs. For example, the solid state of the potassium salt [K{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}]_n is polymeric, as depicted in Scheme 3.³⁸

The K...C contact length in the polymeric potassium complex lies in the range of 3.100–3.468 Å. The ³¹P{¹H} NMR spectrum of the polymeric potassium complex exhibits only one signal at $\delta = -17.5$ ppm, suggesting the symmetric coordination of the ligand in the solution. ³¹P{¹H} of the polymeric potassium is slightly upfield shifted compared to its starting ligand, $\delta = -16.7$ ppm. In contrast, the deprotonation of the

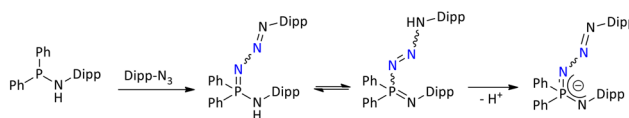

Scheme 3 Syntheses of Li, Na and K complexes of {Ph₂P(ArN)₂} (Ar = 2,6-*i*-Pr₂C₆H₃ and 2,4,6-Me₃C₆H₂).³⁸

{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}H ligand with *n*-BuLi and Na(SiMe₃)₂ resulted in the formation of dimeric complexes [Li{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}]₂ and [Na{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}]₂, respectively. However, upon recrystallization, the later mother-liquor of the dimeric lithium complex [Li{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}]₂ resulted in the formation of unusual crystals of [Ph₂P(2,6-*i*-Pr₂C₆H₃N){2,6-*i*-Pr₂C₆H₃N(Ph₂P)(N=N-2,6-*i*-Pr₂C₆H₃)}Li₂] and [(2,6-*i*-Pr₂C₆H₃N(Ph₂P)(N=N-2,6-*i*-Pr₂C₆H₃))₂Li₂]. The formation of these phosphazide products was attributed to the incomplete N₂ evolution during the Staudinger reaction of ligand formation (Scheme 4).

Additionally, the THF adducts [Li{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}(thf)] and [Li{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}(thf)₂] were isolated either by performing the reaction in *n*-hexane/THF or by the addition of THF to the dimeric [Li{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}]₂ complex. The dimeric molecular structure of the sodium corresponding complex exhibited Na...η⁶-Dipp-arene interaction with the second ligand having an average Na...C centroid distance of 2.50 Å.

Moreover, the deprotonation of {Ph₂P(2,4,6-Me₃C₆H₂N)₂}H with *n*-BuLi in *n*-hexane resulted in the formation of a dimeric complex, [Li₂{Ph₂P(2,4,6-Me₃C₆H₂N)₂}]₂. The treatment of the {Ph₂P(2,4,6-Me₃C₆H₂N)₂}H ligand with Na{N(SiMe₃)₂} in toluene resulted in the formation of a homoleptic sodium complex, [Na₂{Ph₂P(2,4,6-Me₃C₆H₂N)₂}], and the molecular structure of this homoleptic complex was undetermined. However, the THF adduct of the sodium complex could be identified by recrystallizing the product in THF. Additionally, the potassium complex crystallized in polymeric form [K{Ph₂P(2,4,6-Me₃C₆H₂N)₂}]_n similar to [K{Ph₂P(2,6-*i*-Pr₂C₆H₃N)₂}]_n.

Furthermore, when the ligand {Ph₂P(Me₃SiN)₂}H was deprotonated with *n*-BuLi, NaH, KH, Rb, and Cs, the coordination

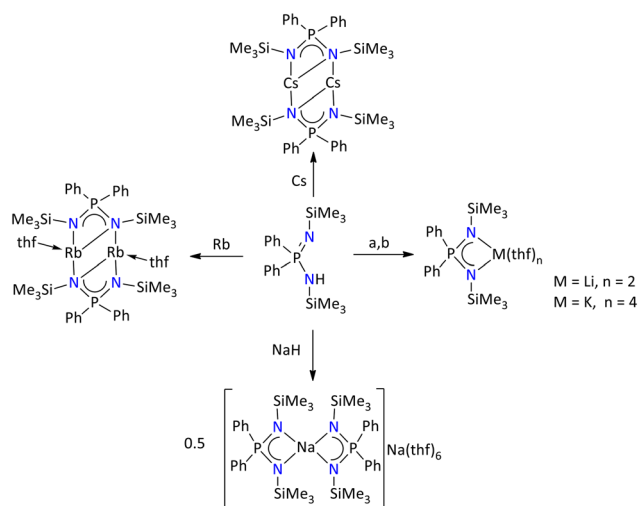

Scheme 4 Formation of phosphazide through incomplete N₂ evolution during the Staudinger reaction.³⁸

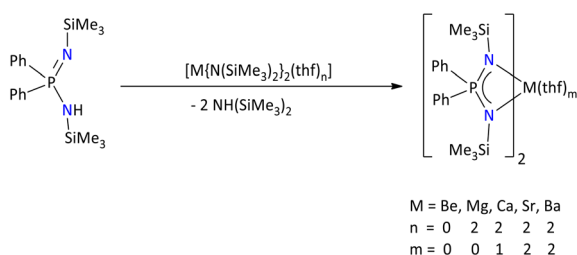

pattern in the series from Li to Cs complexes exhibits a non-uniform trend (Scheme 5).⁴¹ The molecular structures of the lithium and potassium complexes exhibit monomeric forms, $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}\text{Li}(\text{thf})_2]$ and $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}\text{K}(\text{thf})_4]$, where the central metal ions are coordinated by two and four THF molecules, respectively. However, the sodium complex nonuniformly crystallized as highly reactive sodium/sodium ion pair $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}_2\text{Na}][\text{Na}(\text{thf})_6]$. In this ion paired sodium complex, the metal ions exist in two different coordination states, one sodium is octahedrally coordinated by six THF molecules, whereas the other ion is tetrahedrally coordinated by four nitrogen atoms of the iminophosphonamide ligand. Conversely, Rb and Cs metal complexes are found in dimeric $[\{\text{Ph}_2\text{P}(\text{Me}_3\text{SiN})_2\}\text{Rb}(\text{thf})_2]_2$ and $[\{\text{Ph}_2\text{P}(\text{Me}_3\text{SiN})_2\}\text{Cs}]_2$ forms.

Iminophosphonamide alkaline earth metal complexes are generally synthesized by deprotonating the relevant iminophosphonamides with alkaline earth metal amides, $[\text{M}\{\text{N}(\text{SiMe}_3)_2\}_2]$.

The alkaline earth metals ($\text{M} = \text{Be}, \text{Mg}, \text{Ca}, \text{Sr}, \text{and Ba}$), as opposed to alkali metal complexes of the $\{\text{Ph}_2\text{P}(\text{Me}_3\text{SiN})_2\}^-$ ligand, show a consistent coordination pattern (Scheme 6).⁴² The alkaline earth metal complexes exist in a mononuclear form with additional coordination of THF molecules, $[\{\text{Ph}_2\text{P}$

Scheme 5 Iminophosphonamide complexes of alkali metals: (a) *n*-BuLi and (b) KH.⁴¹

Scheme 6 Iminophosphonamide complexes of alkaline earth metals.⁴²

$(\text{NSiMe}_3)_2\}_2\text{M}(\text{thf})_m]$, depending on the ionic radius of central metals.

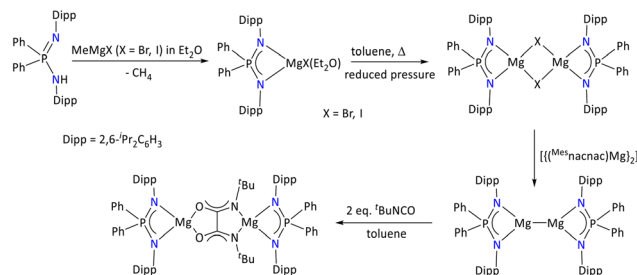

Furthermore, Stasch has incorporated sterically protected iminophosphonamide ligands such as $\{\text{Ph}_2\text{P}(2,6\text{-}i\text{-Pr}_2\text{C}_6\text{H}_3\text{N})_2\}^-$ to stabilize the low-valent $[\text{Mg}]^{+1}$ complexes.⁴³

In this regard, the iminophosphonamide ligand was first deprotonated by MeMgX ($\text{X} = \text{Br}$ and I), which resulted in the formation of $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{-Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{MgX}(\text{Et}_2\text{O})]$. To form an ether-free $\text{Mg}(\text{II})$ complex, the ether adduct of the iminophosphonamide $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{-Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{MgX}(\text{Et}_2\text{O})]$ complex was heated in toluene under reduced pressure, which afforded $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{-Pr}_2\text{C}_6\text{H}_3\text{N})_2\}_2\text{Mg}_2(\mu\text{-X})_2]$. One electron reduction of the halide bridged magnesium complex was performed using $[\{(\text{Mes})\text{nacnac}\}\text{Mg}\}_2]$, which resulted in the low valent magnesium $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{-Pr}_2\text{C}_6\text{H}_3\text{N})_2\}_2\text{Mg}_2]$ complex (Scheme 7). The stability of the low valent magnesium species could be attributed to the P(v) center and steric and kinetic factors of the iminophosphonamide ligand. The $\text{Mg}(\text{I})$ species was characterized by multinuclear NMR spectroscopy and single-crystal X-ray diffraction. The observed Mg-Mg bond distance, 2.8445(9) Å, in the complex is also in the range of previous reports.^{43–46} Moreover, when two equivalents of *tert*-butyl isocyanate reacted with $\text{Mg}(\text{I})$ species, it resulted in the formation of colorless C-C-coupled product $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{-Pr}_2\text{C}_6\text{H}_3\text{N})_2\}_2\text{Mg}_2(\text{N}^t\text{BuCO})_2]$. This product has a bridging *tert*-butyl isocyanate fragment that coordinates the Mg^{2+} centers *via* N, N' and O, O' coordination modes.

This dimeric magnesium complex, $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{-Pr}_2\text{C}_6\text{H}_3\text{N})_2\}_2\text{Mg}_2]$ was also used to examine the mechanisms of anionic ligand exchange and fullerene reduction.⁴⁷

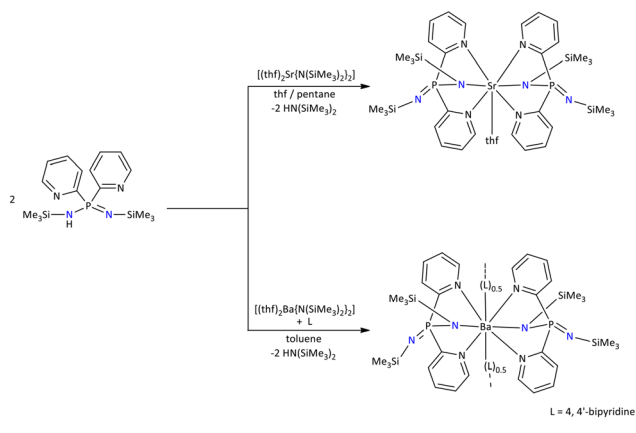

In 2001, Stalke's group altered the coordination ability of the $\{\text{Ph}_2\text{P}(\text{Me}_3\text{SiN})_2\}^-$ iminophosphonamide ligand, by replacing the phenyl substituents of phosphorous with pyridyl moieties; thus, a novel *Janus head* $\{\text{Py}_2\text{P}(\text{Me}_3\text{SiN})_2\}^-$ ligand was reported.⁴⁸ The ligand was synthesized by the reaction of di(2-pyridyl)phosphane with 2 equiv. of trimethylsilylazide *via* the Staudinger method. The NPN coordination pocket in the $\{\text{Py}_2\text{P}(\text{Me}_3\text{SiN})_2\}^-$ ligand and two distant pyridyl substituents indicate that the *Janus head* ligand exhibits two possible chelating coordination pockets.

At room temperature, the protonated *Janus*-type ligand reacts with $[\text{M}\{\text{N}(\text{SiMe}_3)_2\}_2]$ ($\text{M} = \text{Sr}$ or Ba) furnishing $[\{\text{Py}_2\text{P}$

Scheme 7 Low-valent magnesium iminophosphonamide complexes and their reactivity.⁴³

Scheme 8 Janus head iminophosphonamide-based alkaline earth metal complexes.⁴⁸

$[(\text{NSiMe}_3)_2]_2\text{Sr}(\text{thf})$ and $[\{\text{Py}_2\text{P}(\text{NSiMe}_3)_2\}_2\text{Ba}(4,4'\text{-bipy})]_n$ complexes. The 4,4'-bipyridine ligands help to reveal a zigzag polymeric arrangement in the solid-state structure of the barium complex (Scheme 8).⁴⁸

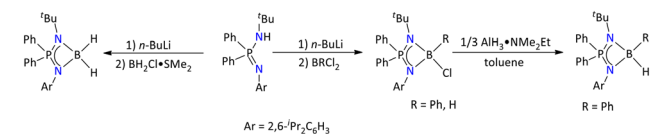

2.2. p-Block: group 13 and 14 compounds of the iminophosphonamides

2.2.1 Iminophosphonamide complexes of group 13 metals.

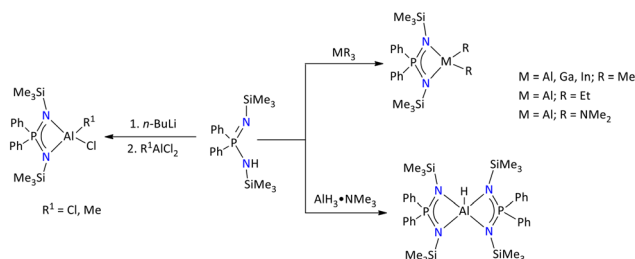

The group 13 metal complexes of the iminophosphonamide typically form four-membered metalacyclic rings. In this context, Singh's group has reported various boron compounds of the iminophosphonamide.⁴⁹ As depicted below, the reaction of $\text{HBCl}_2\cdot\text{SMe}_2$, PhBCl_2 , and $\text{H}_2\text{BCl}\cdot\text{SMe}_2$ with a lithium salt of the iminophosphonamine $\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{Bu})\}\text{H}$ prepared *in situ* resulted in salt metathesis and afforded chloro borane, chlorophenyl borane and dihydro borane complexes of the iminophosphonamide, respectively. Moreover, treatment of the chlorophenyl borane complex with $\text{AlH}_3\cdot\text{NMe}_2\text{Et}$ afforded a phenyl borane complex (Scheme 9).

The formation of all these complexes was confirmed by multinuclear NMR and IR spectroscopy and HRMS, and the molecular structures of all these complexes were determined by single-crystal X-ray diffraction. The molecular structures suggested that the boron center adopts tetrahedral geometry for all these compounds.

The aluminum complexes of the iminophosphonamide $\{\text{Ph}_2\text{P}(\text{Me}_3\text{SiN})_2\}^-$ were reported by H. Roesky. These complexes were obtained either by a base elimination reaction between the iminophosphonamine $\{\text{Ph}_2\text{P}(\text{Me}_3\text{SiN})_2\}\text{H}$ and trialkyl/triamine precursors of group 13 or by salt metathesis processes involving group 13 metal halides and *in situ* produced lithium iminophosphonamide (Scheme 10).^{50,51} The tetracoordinated dimethyl complexes $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}\text{Me}_2\text{M}]$ ($\text{M} = \text{Al}, \text{Ga}, \text{or In}$) exhibited distinct melting points. By determining the matching cryoscopic molecular weight, the monomeric character of these metal complexes was verified.⁵⁰ The aluminum monohydride complex, which was synthesized by the reaction of $[\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\text{H}]$ and $\text{AlH}_3\cdot\text{NMe}_3$, adopted a dis-

Scheme 9 Syntheses of iminophosphonamide-based borane complexes.⁴⁹

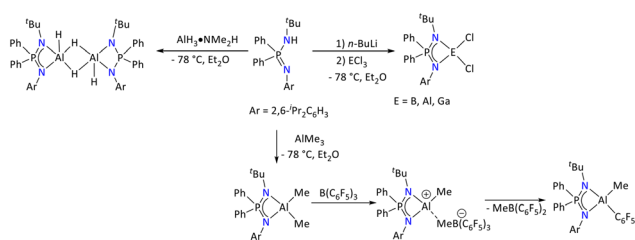

Scheme 10 Synthesis of group 13 iminophosphonamide complexes.⁵¹

torted trigonal bipyramidal geometry. The P–N bond lengths for each of these complexes are consistent with previously reported single and double bond lengths.⁵² Few group 13 metal complexes based on distinct iminophosphonamide backbones such as $\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{Bu})\}^-$ ²⁶ and $\{\text{Ph}(\text{N}^t\text{Bu})(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}^-$ ⁵³ have been structurally characterized.

In this context, the deprotonation of the iminophosphonamine ligand $\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{BuH})\}^-$ with $\text{AlH}_3\cdot\text{NMe}_2\text{H}$ in an equivalent ratio resulted in the formation of dimeric aluminum complex $[\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{Bu})\}\text{AlH}(\mu\text{-H})\text{AlH}\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{Bu})\}]$ based on the solid-state structure (Scheme 11). The molecular structure revealed that each aluminum center adopted a distorted trigonal bipyramidal geometry.

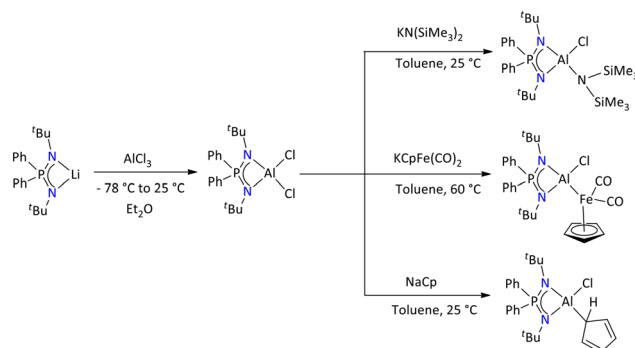

The terminal hydride, one of the bridging hydrides and one of the nitrogen atoms of the iminophosphonamide ligand adopted the equatorial plane, whereas the remaining bridging hydride and another nitrogen of the ligand occupied the axial plane with the N–Al–H bond angle of $159.50(2)^\circ$. The aluminum hydride signals were assigned to a broad singlet at $\delta = 5.20$ ppm in the ^1H NMR spectrum. Further deprotonation of the ligand $\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{BuH})\}$ with AlMe_3 furnished facile formation of $[\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{Bu})\}\text{AlMe}_2]$. The

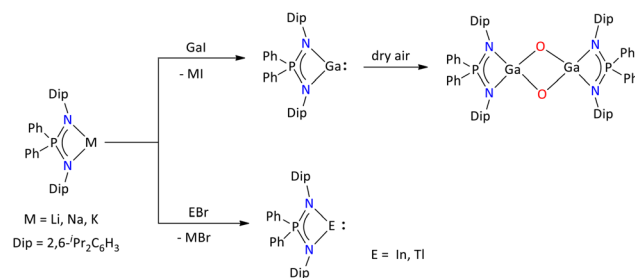

Scheme 11 Group 13 metal complexes substituted by the bulky iminophosphonamide ligand.²⁶

Al–Me resonance appeared as a singlet at $\delta = 0.12$ ppm in the ^1H NMR spectrum of the complex. Furthermore, the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of the complex showed a single peak at $\delta = 30.23$ ppm. Additionally, treatment of $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{Bu})\}\text{AlMe}_2]$ with $\text{B}(\text{C}_6\text{F}_5)_3$ resulted in the formation of cationic aluminum species $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{Bu})\}\text{AlMe}]^+[\text{B}(\text{C}_6\text{F}_5)_3\text{Me}]^-$, which was characterized by multinuclear NMR spectroscopy. It was observed that the cationic species slowly converts into neutral tetracoordinated aluminum species *via* Me and C_6F_5 exchange. Additionally, the salt metathesis reaction between the lithium salt generated *in situ* and ECl_3 (E = B, Al, and Ga) furnished the corresponding metal dichloride complexes, $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})(\text{N}^t\text{Bu})\}\text{ECl}_2]$ (E = B, Al, and Ga). The identity of these complexes was confirmed by multinuclear NMR and IR spectroscopy, HRMS and X-ray diffraction techniques.

Vrána *et al.* investigated the reactivity of bis(organoamino)phosphanes $\text{PhP}(\text{NHR})(\text{NHR}')$ (R = R' = ^tBu ; R = ^tBu , R' = $2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$; R = R' = Ph) and $^t\text{BuP}(\text{NHDip})_2$ with Al(III) compounds (Scheme 12).⁵³ In this regard, the reaction of $\text{PhP}(\text{NH}^t\text{Bu})_2$ and $\text{PhP}(\text{NH}^t\text{Bu})(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{NH})$ with AlMe_3 resulted in the formation of $[\{\text{PhP}(\text{NHR})(\text{NR}')\}\text{AlMe}_2]$ (R = R' = ^tBu ; R = ^tBu , R' = $2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$) complexes *via* methane elimination. Furthermore, upon heating, these complexes showed H atom migration from nitrogen to the phosphorous center, which resulted in $[\{\text{PhHP}(\text{NR})(\text{NR}')\}\text{AlMe}_2]$ (R = R' = ^tBu ; R = ^tBu , R' = $2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$) complexes. In contrast to this, when $\text{PhP}(\text{NHPh})_2$ was reacted with AlMe_3 , it resulted in the formation of an intermediate adduct, $[\text{Ph}(\text{H})\text{P}(\text{NHPh})(=\text{NPh})\text{AlMe}_3]$, which was converted into $[\text{Ph}(\text{H})\text{P}(\text{NPh})_2\text{AlMe}_2]$ due to the first hydrogen atom migration followed by methane elimination. Furthermore, hydrogen atom migration was observed when the bis(organoamino)phosphanes $\{\text{R}''\text{P}(\text{NHR})(\text{NHR}')\}$ (R'' = Ph, R = R' = ^tBu ; R'' = Ph, R = ^tBu , R' = $2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$ and R'' = ^tBu , R = R' = $2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$) were partially deprotonated by *n*-BuLi, whereupon the reaction with AlCl_3 resulted in $[\{\text{R}''\text{HP}$

Scheme 13 Syntheses of the aluminum(III) monochloride complex bearing a nucleophile, $[\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}\text{AlCl}(\text{Nu})]$.⁵⁴

Scheme 14 Syntheses of the monovalent heavier group 13 iminophosphonamide complexes.⁵⁵

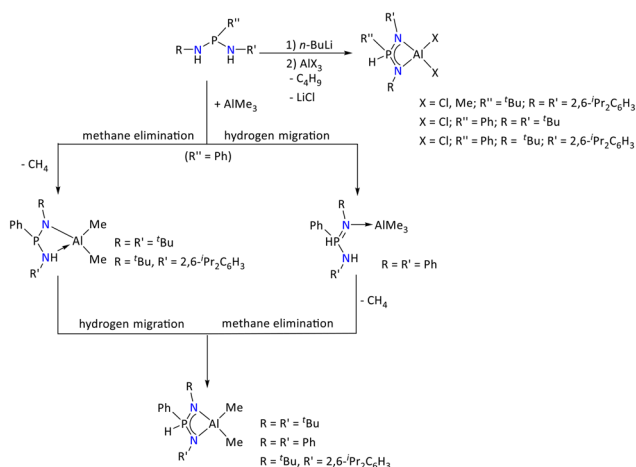

$(\text{NR})(\text{NR}')\}\text{AlCl}_2]$ (R'' = Ph, R = R' = ^tBu ; R'' = Ph, R = ^tBu , R' = $2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$ and R'' = ^tBu , R = R' = $2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3$).

Apart from this, Nakata's group has demonstrated nucleophilic substitution reactions of $[\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}\text{AlCl}_2]$ using various nucleophiles (Nu) such as $\text{N}(\text{SiMe}_3)_2^-$, $\{\text{Fe}(\text{CO})_2\text{Cp}\}^-$ and Cp^- that resulted in the formation of an aluminum(III) monochloride complex bearing a nucleophile, $[\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}\text{AlCl}(\text{Nu})]$ (Scheme 13).⁵⁴ The identity of all these aluminum(III) mono- and di-chloride complexes was confirmed by various spectroscopic techniques and the molecular structures were identified by single-crystal X-ray diffraction.

Interestingly, by taking advantage of the sterically protected iminophosphonamide $\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}^-$ ligand, Stasch's group reported monovalent group 13 complexes $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{E}]$ (Ga(I), In(I), and Tl(I)) (Scheme 14).⁵⁵

Other than the monomeric form for Ga(I), a weakly bonded dimer was obtained, which was structurally characterized. The Ga(I) complex upon exposure to dry air affords an oxidized Ga(III) complex, $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{Ga}(\mu_2\text{-O})_2\text{Ga}\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}]$.

2.2.2 Iminophosphonamide compounds of group 14 elements. The heavier analogues of carbene compounds are collectively termed tetrylenes $[\text{R}_2\text{E}]$ with (E = Si, Ge, Sn and Pb with R = supporting ligand). Lappert and co-workers in 1974 led the field of tetrylenes and reported the first germylene and stanylenes,^{56–60} after which, the amidine-stabilized divalent group 14 compounds $[\{\text{PhC}(\text{N}^t\text{Bu})_2\}\text{ECl}]$, (E = Si, Ge, and Sn)

Scheme 12 Reactivity study of Al(III) compounds with bis(organoamino)phosphanes, $\text{PhP}(\text{NHR})(\text{NHR}')$.⁵³

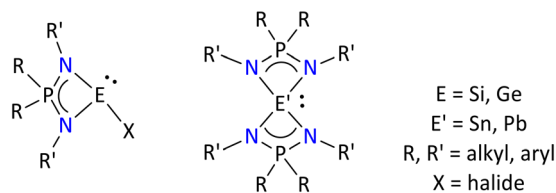

Fig. 3 Literature-known tetrylenes based on iminophosphonamides.^{65–70}

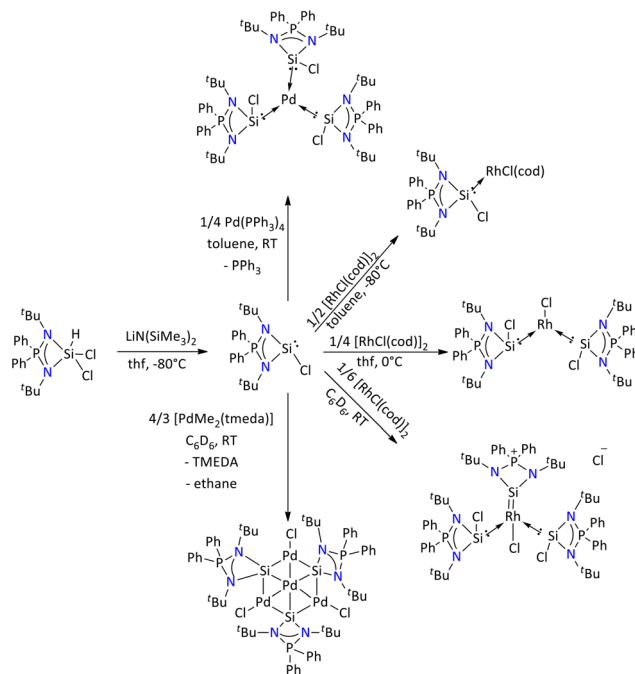

were reported.^{61–64} Since then, during the past 20 years, the corresponding chemistry has significantly expanded.^{61–64} As compared to well-known amidinato-tetrylenes, the examples of tetrylenes stabilized by iminophosphonamide are few (Fig. 3).

These examples include the structurally characterized germylene $[\text{Ph}_2\text{P}(\text{N}^t\text{Bu})(2,6\text{-}^i\text{Pr}_2\text{C}_6\text{H}_3\text{N})\text{GeX}]$ (where $X = \text{Cl, O}^t\text{Bu, OTf}$), $[(\text{RO})_2\text{P}(\text{NSiMe}_3)_2]\text{GeCl}$, $[(\text{RO})(\text{Me}_3\text{SiO})\text{P}(\text{NSiMe}_3)_2]\text{GeCl}$, ($R = ^t\text{Pr}$) and stannylene $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}_2\text{Sn}]$ and $[\{(\text{Ph})(\text{R})\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SnX}]$ (where $R = \text{CH}_2\text{Ph}$ or $8\text{-C}_9\text{H}_6\text{N}$; $X = \text{Cl}$ or $\text{N}(\text{SiMe}_3)_2$) compounds.

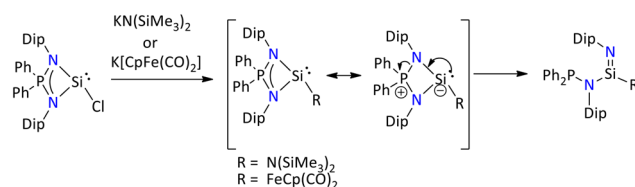

Recently, an iminophosphonamide variant (*i.e.* $[\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}]$) of the amidinate $[\{\text{PhC}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}]$ has been reported by Nakata's group.⁷¹ The study suggested that the chlorosilylene supported by iminophosphonamide has stronger σ -donor ability in comparison to common N-heterocyclic carbenes (NHCs) and other NHSis. Further when the synthesized silylene reacted with $\frac{1}{2}$ equivalent of $[\text{RhCl}(\text{cod})]_2$, it led to the formation of a chlorosilylene-Rh(i) complex, $[\text{RhCl}(\text{cod})\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}]$. The $^{29}\text{Si}\{^1\text{H}\}$ NMR spectrum of the complex exhibited a doublet at $\delta = 27.3$ ppm, which is due to the coupling of ^{29}Si with ^{103}Rh and ^{31}P ($J_{\text{Si-Rh}} = 114.5$ Hz; $J_{\text{Si-P}} = 13.4$ Hz). Further, the cationic tris(silylene)-Rh(i) complex, $[\text{RhCl}\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_3]^+$, and the 14-electron Y-shaped Rh(i) complex, $[\text{RhCl}\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}]_2$, were produced by the reactions of $\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}$ with $[\text{RhCl}(\text{cod})]_2$ in 1/4 and 1/6 equivalents, respectively. Additionally, treating the $\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}$ with $[\text{Pd}(\text{PPh}_3)_4]$ resulted in the formation of a homoleptic Pd(0) complex, $[\text{Pd}\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_3]$. Interestingly, when the chlorosilylene was treated with $[\text{PdMe}_2(\text{tmeda})]$, it afforded a μ_3 -silylene-bridged tetranuclear palladium complex, with different oxidation states of the palladium centre (Scheme 15).⁷² The XPS analysis of the cluster suggested the presence of mixed oxidation states, Pd(0) and Pd(II), in the complex.

Further, Nakata's group has demonstrated that when the salt metathesis reaction was performed between chlorosilylene and $\text{KN}(\text{SiMe}_3)_2$ or $\text{K}[\text{CpFe}(\text{CO})_2]$, the formation of silaimine instead of expected silylene was seen (Scheme 16). It was observed that the conversion of silaimine occurred *via* ring opening rearrangement of sterically hindered four-membered silylene. The DFT study suggest that combination of steric hindrance and the electronic factor of the substituents is the main reason for this intramolecular P–N bond cleavage of the intermediate silylene.⁷³

It is also demonstrated that the synthesis of $[\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiX}]$ ($X = \text{Br}$ and I) by heavier halo substitution of the chlorosi-

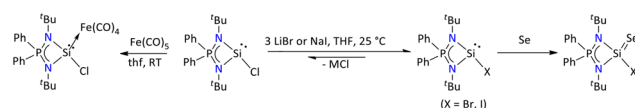

Scheme 15 Syntheses of an iminophosphonamide monochloride silylene and its reactivity.^{71,72}

Scheme 16 Generation of silaimine *via* intramolecular P–N bond cleavage of iminophosphonamido silylene.⁷³

lylene could be achieved *via* a halogen exchange reaction between the chlorosilylene $[\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}]$ and alkali halides (Scheme 17). The resulting Si–X bonds of $[\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiX}]$ ($X = \text{Br, I}$) are considerably longer than expected possibly due to repulsion between the Si and the halogen lone pairs.⁷⁴ Further, the oxidative addition of these heavier halo silylene with elemental selenium afforded a colorless product of bromo- and iodo-silylene selone. Moreover, the reaction of chlorosilylene with $\text{Fe}(\text{CO})_5$ in THF resulted in the formation of silylene-tetracarbonyliron(0), $[\text{Fe}(\text{CO})_4\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}]$, which is characterized by various spectroscopic techniques, and the molecular structure was determined by single-crystal X-ray diffraction.⁷⁵

Scheme 17 Reactivity of $[\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})_2\}_2\text{SiCl}]$.^{74,75}

Furthermore, other than Si(II), Nakata's group explored the iminophosphonamide ligand with its heavier analogs such as Ge(II), Sn(II), and Pb(II) (Schemes 18 and 20).^{76–78} The salt elimination reaction between the lithium salt of the iminophosphonamide ligand and GeCl₂-dioxane gave the three-coordinated chlorogermynes of the type {Ph₂P(NR)₂GeCl} (R = ^tBu; R = Dipp = 2,6-ⁱPr₂C₆H₃).⁷⁸ When {Ph₂P(N^tBu)₂GeCl} was reacted with ½ equivalent of [Rh(cod)Cl]₂ the formation of a chlorogermylene-Rh(I) complex, [RhCl(cod){Ph₂P(N^tBu)₂GeCl}], was seen. In contrast to this, when {Ph₂P(NDipp)₂GeCl} was treated with ½ equivalent of [Rh(cod)Cl]₂ in the presence of CO, it resulted in the formation of a five-membered germarhodacycle, [{Ph₂P(NDipp)₂}Rh(CO)₂GeCl₂] (Scheme 18).

The application of a germylene-based ligand was also demonstrated by using the chlorogermylene-Rh(I) complex [RhCl(cod){Ph₂P(N^tBu)₂GeCl}] as a catalyst to hydrosilylate and hydroborate diphenylacetylene.

The lithium salt of the ligand, [Li{Ph₂P(2,6-ⁱPr₂C₆H₃N)(N^tBu)}], generated *in situ* was treated with one equivalent of GeCl₂-dioxane to give the germylene monochloride [{Ph₂P(2,6-ⁱPr₂C₆H₃N)(N^tBu)}GeCl].⁶⁵ Its reactivity was further investigated towards generating adducts with transition metals, oxidation, and salt metathesis processes (Scheme 19).

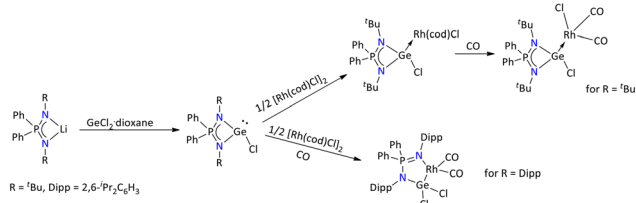

More recently, Driess and coworkers have reported the synthesis of a new chelating bis(iminophosphonamido-germylene)xanthene ligand, {Ph₂P(N^tBu)₂Ge(II)(Xant)Ge(II)(N^tBu)₂PPh₂}, (Xant = 9,9-dimethyl-xanthene-4,5-diyl).⁷⁹ The redox noninnocent character of the ligand was used to stabilize monoatomic, two-coordinate Bi(I) and Bi(II) species. The nucleophilic nature of the Bi(I) species was investigated

through redox reactions with AgOTf and MeOTf, leading to the formation of Bi(III) species.⁷⁹

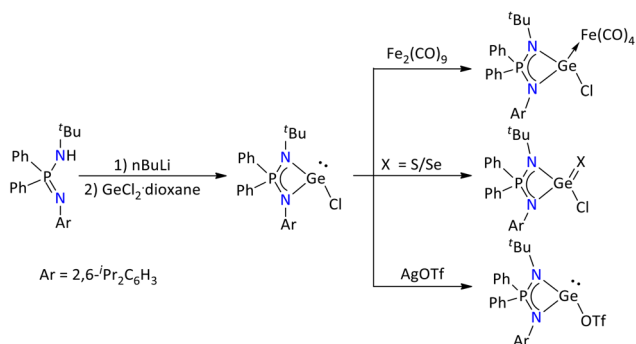

Moreover, [{Ph₂P(N^tBu)₂}SnCl], synthesized by Nakata's group, was employed as a precatalyst for the hydroboration of carbonyls and imines. The result of the DFT calculations proposed that the hydroboration of carbonyl involves [{Ph₂P(N^tBu)₂}SnH] as an intermediate, which proceeded through hydride transfer to carbonyl groups and eventually resulted in the boronate esters.⁷⁶

Apart from this, Nakata's group has reported various low-valent Pb(II) species ligated by the iminophosphonamide {Ph₂P(N^tBu)₂}[−]. The general salt elimination reaction of [{Ph₂P(N^tBu)₂}Li] with PbCl₂ furnished the chloroplumbylene {Ph₂P(N^tBu)₂PbCl}. Further substitution of the chloride with {N(SiMe₃)₂}[−] resulted in the formation of aminoplumbylene [Ph₂P(N^tBu)₂PbN(SiMe₃)₂]. A mono cationic plumbylumylidene [Ph₂P(N^tBu)₂Pb:]⁺ was generated through the chloride abstraction of [Ph₂P(N^tBu)₂PbCl] with NaB(C₆F₅)₄ (Scheme 20). The cationic [Ph₂P(N^tBu)₂Pb:]⁺[B(C₆F₅)₄][−] plumbylumylidene served as an efficient catalyst for the hydroboration of benzophenone and benzaldehyde.⁷⁷

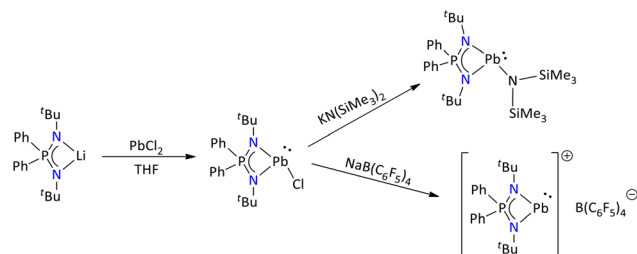

Moreover, tetracoordinated [{Ph₂P(NSiMe₃)₂}₂E] (E = Sn and Pb) complexes of Sn(II) and Pb(II) have been reported by salt metathesis route (Scheme 21).⁶⁷ The ³¹P{¹H} NMR spectrum of [{Ph₂P(NSiMe₃)₂}₂E] showed a single resonance at δ = 25.4 ppm, whereas the ²⁹Si NMR spectrum showed a doublet at δ = −5.2 ppm, with a coupling constant of ²J_{Si–P} = 8 Hz. The tetraenes exist in a distorted trigonal bipyramidal geometry, with the lone pair occupying the equatorial position. The molecular structure of the stanylene and plumbylene showed that both the four membered metalyne (*i.e.*, [{Ph₂P(NSiMe₃)₂}₂M], M = Sn and Pb) planes are twisted with each

other possibly due to the presence of lone pair and steric crowding from SiMe₃ groups.

2.3 Transition metal complexes of the iminophosphonamide ligands

Numerous studies have been conducted on amidinate (NCN)-stabilized transition metal complexes, and their catalytic applications in a range of organic transformations have been documented.^{80,81} The transition metal chemistry of the iminophosphonamide (NPN) ligand is still in its infancy compared to amidinate ligands. However, some iminophosphonamide transition metal complexes have been used as catalysts in recent decades, for example in alkene polymerizations,^{82,83} cyclopropanation reactions,^{84,85} and olefin oligomerizations.⁸⁶

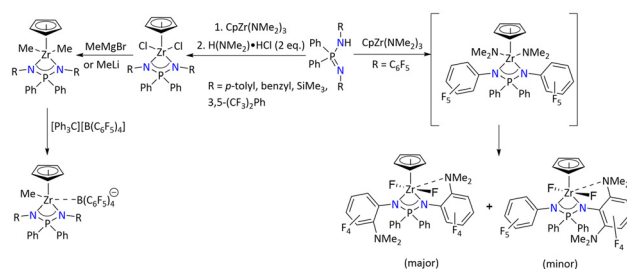

2.3.1 Syntheses of Ti, Zr, and Hf complexes. In 1999, Collins' group reported the synthesis of iminophosphonamide complexes of group 4 metals (Ti and Zr) *via* the amine elimination route (Scheme 22). The zirconium complexes of bis(iminophosphonamide), [$\text{Ph}_2\text{P}(\text{N-}p\text{-tolyl})_2\text{ZrCl}_2$] and mixed iminophosphonamide [$\text{Cp}\{\text{Ph}_2\text{P}(\text{N-}p\text{-tolyl})_2\}\text{ZrCl}_2$] were characterized by single-crystal X-ray diffraction. The synthesized complexes exhibited efficient catalytic activity towards the polymerization of ethylene in the presence of MAO.⁸⁷

Also the bis(iminophosphonamide) complexes, [$\text{Ph}_2\text{P}(\text{NR})_2\text{MCl}_2$] (R = *p*-tolyl, benzyl and M = Ti, Zr) were investigated towards ethylene polymerization. The result of catalysis suggested 50 to 100 times higher catalytic activity of the [$\text{Ph}_2\text{P}(\text{NR})_2\text{ZrCl}_2$] (R = *p*-tolyl, benzyl) complex than its Ti analogue.

Collins' group also reported a range of group 4 metal complexes coordinated by bis(iminophosphonamide). Piano-stool-type iminophosphonamide compounds were formed. In this regard, the amine elimination reaction between variably substituted iminophosphonamine, $\{\text{Ph}_2\text{P}(\text{NR})_2\}\text{H}$ (R = *p*-tolyl, benzyl, SiMe₃, C₆F₅, 3,5-(CF₃)₂Ph) and CpZr(NMe₂)₃ followed by metathesis with excess Me₂NH·HCl resulted in the formation of [$\text{Cp}\{\text{Ph}_2\text{P}(\text{NR})_2\}\text{ZrCl}_2$] (R = *p*-tolyl, benzyl, SiMe₃, C₆F₅, 3,5-(CF₃)₂Ph). During the amine elimination, the intermediate [$\text{Cp}\{\text{Ph}_2\text{P}(\text{NC}_6\text{F}_5)_2\}\text{Zr}(\text{NMe}_2)_2$] rearranged in a novel terminal difluoride complex, [$\text{Cp}\{\text{Ph}_2\text{P}(\text{NC}_6\text{F}_4\text{NMe}_2)_2\}\text{ZrF}_2$], as described in Scheme 23.

Furthermore, when [$\text{Cp}\{\text{Ph}_2\text{P}(\text{NR})_2\}\text{ZrCl}_2$] (R = *p*-tolyl, benzyl, SiMe₃, C₆F₅, 3,5-(CF₃)₂Ph) was reacted with MeMgBr or MeLi, it furnished the corresponding dialkyl complex.^{88,89}

It was observed that the bis(iminophosphonamide)-ligated zirconium complexes, [$\text{Ph}_2\text{P}(\text{NR})_2\text{ZrX}_2$] (R = *p*-tolyl, benzyl, C₆F₅; X = Cl and Me) and piano-stool-type iminophosphonamide-ligated zirconium complexes, [$\text{Cp}\{\text{Ph}_2\text{P}(\text{NR})_2\}\text{ZrX}_2$] (R =

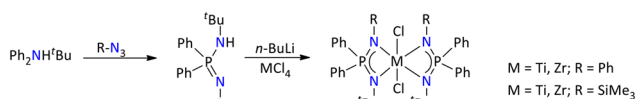

Scheme 23 Piano-stool-type iminophosphonamide complexes of zirconium.^{88,89}

p-tolyl, benzyl, C₆F₅; X = Cl and Me), showed good catalytic activity towards ethylene polymerization in the presence of activators such as [$\text{Ph}_3\text{C}\{\text{B}(\text{C}_6\text{F}_5)_4\}$] or PMAO.

The iminophosphonamide complexes of titanium and zirconium of the form [$\{\text{Ph}_2\text{P}(\text{N}^t\text{Bu})(\text{NR})_2\text{MCl}_2\}$] (M = Ti, Zr and R = Ph, SiMe₃) were synthesized by reacting the corresponding iminophosphonamide ligand and MCl₄ (M = Ti and Zr) (Scheme 24).⁹⁰

The ethylene polymerization using these complexes as catalysts did not give a satisfactory result, which was anticipated due to steric crowding around the metal center.

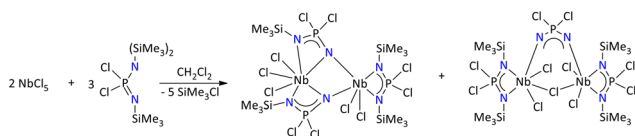

Furthermore, Manners' group reported perhalogenated bis(iminophosphonamide) complexes, [$\{\text{Cl}_2\text{P}(\text{NSiMe}_3)_2\}\text{MCl}_3$]·THF (M = Ti, Zr and Hf) and [$\{\text{Cl}_2\text{P}(\text{NSiMe}_3)_2\}\text{NbCl}_4$], by the reaction of $\{\text{Cl}_2\text{PN}(\text{SiMe}_3)_2(=\text{NSiMe}_3)\}$ with corresponding metal halides in dichloromethane. The formation of these complexes was anticipated as the [3 + 1] cyclocondensation of the ligand and metal center, resulting in the elimination of Me₃SiCl (Scheme 25). Interestingly, a mixture of product formation was observed when 1.5 eq. of the ligand $\{\text{Cl}_2\text{PN}(\text{SiMe}_3)_2(=\text{NSiMe}_3)\}$ was treated with NbCl₅. The reaction mixture exhibited many signals between $\delta = 14.5$ and 6.5 ppm in the ³¹P{¹H} NMR spectrum. Finally, the product was characterized by single-crystal X-ray diffraction, which showed the formation of unusual heterocycles [$\text{Cl}_3\text{Nb}\{\text{N}(\text{SiMe}_3)\text{PCl}_2\text{N}\}_2\text{Cl}_2\text{Nb}\{\text{N}(\text{SiMe}_3)\text{PCl}_2\text{N}(\text{SiMe}_3)\}$] and [$\text{Cl}_2\text{Nb}\{\text{N}(\text{SiMe}_3)\}$].

Scheme 24 Synthesis of Ti and Zr complexes of iminophosphonamides.⁹⁰

Scheme 22 Group 4 (M = Ti and Zr) iminophosphonamide complexes as efficient polymerization catalysts.⁸⁷

Scheme 25 Synthesis of unusual heterocycles of niobium stabilized by iminophosphonamide.⁹¹

$\text{PCl}_2\text{N}(\text{SiMe}_3)_2\}_2\text{-}\mu\text{-Cl}(\text{N}(\text{PCl}_2\text{N}))$; the later complex was considered as the first example of Nb complex containing the six-membered ClNbNPNb ring.⁹¹

2.3.2 Syntheses of Cr, Fe, Ru, Co, and Rh complexes of iminophosphonamide. Gambrotta's group reported various chromium iminophosphonamide complexes by treating the variably substituted iminophosphonamines $\text{Ph}_2\text{PBr}(\text{NHR})_2$ ($\text{R} = \text{'Bu}$, 'Pr , and Ph) with $n\text{-BuLi}$ first. Subsequent reactions with CrCl_2 resulted in the formation of divalent chromium complexes, $[\{\text{Ph}_2\text{PN}(\text{R})_2\}\text{Cr}(\mu\text{-Cl})_2\text{Li}(\text{THF})_2]$ ($\text{R} = \text{'Pr}$ and 'Bu) and $[\{\text{Ph}_2\text{PN}(\text{Ph})_2\}_2\text{Cr}_2(\mu\text{-Cl})_3\text{Li}(\text{DME})_3]$ (Scheme 26).⁸⁶ Similarly, the trivalent chromium complex $[\{\text{Ph}_2\text{PN}(\text{'Bu})_2\}_2\text{Cr}_2(\mu\text{-Cl})_3(\mu_3\text{-Cl})_2\text{Li}(\text{THF})_2]$ was obtained by the reaction of CrCl_3 with a doubly deprotonated ligand. Further treatment of both divalent and trivalent chromium complexes with AlMe_3 resulted in the formation of a homoleptic cationic chromium complex, $[\{\text{Ph}_2\text{PN}(\text{'Bu})_2\}_2\text{Cr}]^+[\text{AlMe}_3\text{Cl}]^-$. The structures of all these complexes were elucidated by X-ray diffraction. Moreover, the catalytic activity of these complexes was screened for the oligomerization of ethylene. The results showed that in the presence of methyl aluminoxane, the divalent chromium complex $[\{\text{Ph}_2\text{PN}(\text{'Bu})_2\}\text{Cr}(\mu\text{-Cl})_2\text{Li}(\text{THF})_2]$ exhibited the best catalytic activity.

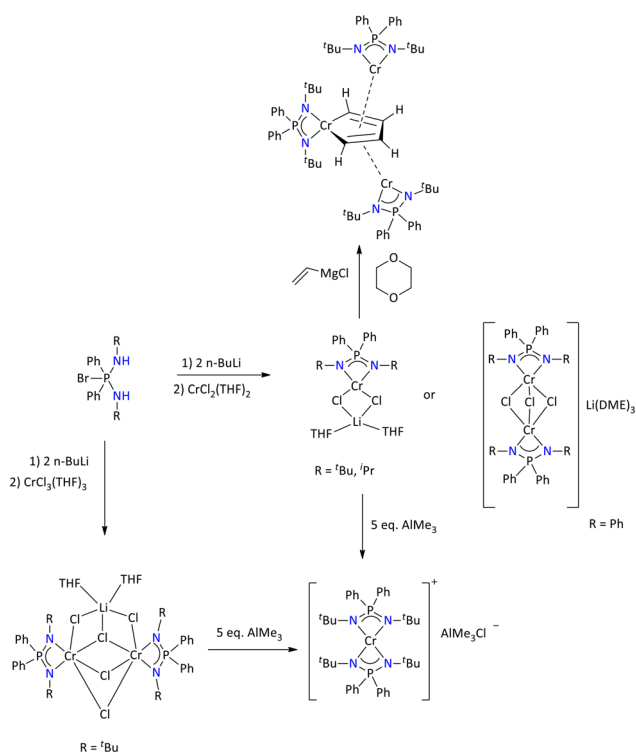

Furthermore, treatment of the divalent chromium complex $[\{\text{PPh}_2\text{N}(\text{'Bu})_2\}\text{Cr}(\mu\text{-Cl})_2\text{Li}(\text{THF})_2]$ with the Grignard reagent $\text{CH}_2=\text{CH-MgCl}$ resulted in the formation of the trinuclear chromium complex $[\pi\text{-}\{\text{Ph}_2\text{P}(\text{N'Bu})_2\}_2\text{Cr}]_2\{\mu, \mu', \eta^4, \eta^4\text{-C}_4\text{H}_4\}[\sigma\text{-}\{\text{Ph}_2\text{P}(\text{N'Bu})_2\}_2\text{Cr}]$. The trinuclear complex was also structurally characterized by single-crystal X-ray diffraction. The molecular

structure of the complex suggests that the one chromium center possessing iminophosphonamide, (*i.e.*, $[\{\text{Ph}_2\text{P}(\text{N'Bu})_2\}\text{Cr}]$), is part of a planar metalla cyclopentadiene ring, whereas the other chromium centers are situated perpendicular of the metalla cycle with π bonds. This complex served as an efficient and selective catalyst for ethylene trimerization.⁹²

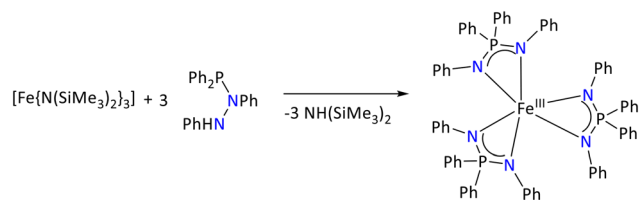

The Fe(III) complex of the iminophosphonamide $[\{\text{Ph}_2\text{PN}(\text{Ph})_2\}_3\text{Fe}]$ was synthesized by treating the iron(III) silylamide $[\text{Fe}\{\text{N}(\text{SiMe}_3)_2\}_3]$ with the phosphinohydrazine $\{\text{NPh}(\text{Ph}_2\text{P})\text{NHPh}\}$ in 1:3 proportion, respectively (Scheme 27). During the deprotonation reaction of the phosphinohydrazines, it rearranged and converted into the iminophosphonamide $\{\text{Ph}_2\text{P}(\text{NPh})_2\}$. The synthesized iron(III) complex was isolated as fine yellow crystals that were stable towards the air. The complexes displayed strong absorptions at 1300 cm^{-1} and 1270 cm^{-1} in their IR spectra, which were attributed to the stretching vibrations of the N–P–N ligand backbone.⁹³

The 16 VE and 18 VE half sandwich complexes of ruthenium containing $[(\eta^6\text{-C}_6\text{Me}_6)\{\text{R}_2\text{P}(\text{NR}')_2\}\text{RuCl}]$ and $[(\eta^6\text{-C}_6\text{Me}_6)\{\text{R}_2\text{P}(\text{NR}')_2\}\text{Ru}]^+[\text{BF}_4]^-$ ($\text{R} = \text{Ph}$, Et and $\text{R}' = p\text{-Tol}$, Me) were synthesized by reacting the appropriate precursor of variably substituted iminophosphonamides with $[(\text{C}_6\text{Me}_6)\text{RuCl}_2]_2$ followed by halide abstraction, respectively (Scheme 28).^{27,94–96} The centroid ($\text{Ru-C}_6\text{Me}_6$) distance falls between $1.662(4)\text{ \AA}$ and $1.675(3)\text{ \AA}$, which is a common range for neutral half-sandwich ruthenium complexes. The Ru-Cl bond in the range of $(2.437\text{--}2.445\text{ \AA})$ of the 18 VE $[(\eta^6\text{-C}_6\text{Me}_6)\{\text{R}_2\text{P}(\text{NR}')_2\}\text{RuCl}]$ complexes is elongated, and dissociates even in an apolar solvent, forming the corresponding 16 VE $[(\eta^6\text{-C}_6\text{Me}_6)\{\text{R}_2\text{P}(\text{NR}')_2\}\text{Ru}]^+[\text{Cl}]^-$ cationic complex that can be readily separated as salts with weakly-coordinating anions such as BF_4^- .

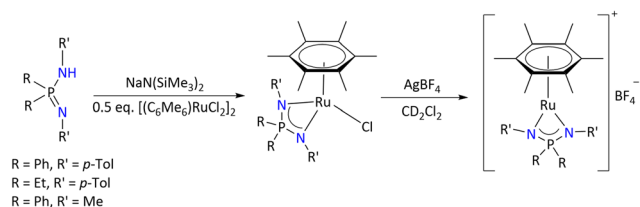

The stability of the 16 VE cation of the ruthenium complex arises from the sufficient π -donation from the iminophospho-

Scheme 26 Chromium complexes of iminophosphonamide as active catalysts for ethylene oligomerization.^{86,92}

Scheme 27 Synthesis of the homoleptic Fe(III) iminophosphonamide complex.⁹³

Scheme 28 Synthesis of the half-sandwich Ru(II) iminophosphonamide complex.²⁷

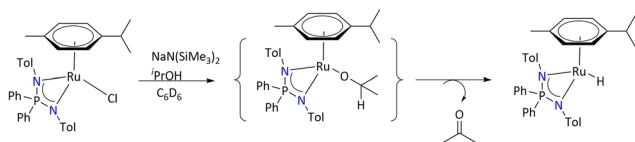

namide ligand. The characterization of these complexes was carried out by NMR spectroscopy, X-ray diffraction, and elemental analysis. The molecular structure of the 16 VE cationic ruthenium complex suggested the two-legged piano-stool-type geometry with the iminophosphonamide ligand perpendicular to the C_6H_6 ring. These complexes also served as efficient catalysts in the ROMP polymerization of norbornene.

Furthermore, Poli's group investigated the ruthenium complex of the iminophosphonamide, $[(\eta^6\text{-Cym})\{\text{Ph}_2\text{P}(\text{N-}p\text{Tol})_2\}\text{RuCl}]$, as a precatalyst for ketone transfer hydrogenation by isopropanol, which revealed the hydridic ruthenium complex, $[(\eta^6\text{-Cym})\{\text{Ph}_2\text{P}(\text{N-}p\text{Tol})_2\}\text{RuH}]$, as the active catalyst in a basic medium (Scheme 29).⁹⁷ This ruthenium hydride complex is stabilized by dihydrogen bonding in the isopropanol. The transfer hydrogenation mechanism was investigated by NMR spectroscopy and DFT calculations.

Moreover, Poli and Kalsin's group reported a variety of ruthenium arene complexes, $[(\text{Arene})\text{RuCl}\{\text{R}_2\text{P}(\text{NR}')_2\}]$ bearing various substituents on iminophosphonamide ligands and a variety of arene rings (Fig. 4).⁹⁴

The general synthesis of these complexes is shown in Scheme 30. These complexes were characterized by multinuclear NMR spectroscopy and X-ray diffraction analysis. A comparative investigation of these complexes as precatalysts was carried out towards acetophenone transfer hydrogenation in basic and base-free isopropanol.

The study revealed two distinct reaction pathways depending on the basicity of the *N*-substituents. In the case of $[(\text{Arene})\text{RuCl}\{\text{R}_2\text{P}(\text{NR}')_2\}]$ ($\text{R}' = \text{aryl}$), the active catalyst was observed only once the neutral hydride $[(\text{Arene})\text{RuH}\{\text{R}_2\text{P}(\text{NR}')_2\}]$ is generated in basic isopropanol, whereas when one of the nitrogen substituents is Me (*i.e.*, $\text{R}' = \text{Me}$) in $[(\text{Arene})\text{RuCl}\{\text{R}_2\text{P}(\text{NR}')_2\}]$, it readily catalyzed the reaction without base (Scheme 31).

Scheme 31 Possible reaction pathways for acetophenone hydrogenation-catalyzed Ru(II) iminophosphonamide.⁹⁴

In the literature, the number of structurally characterized Co(II) complexes is limited to a few iminophosphonamide backbones such as $\{\text{Ph}_2\text{P}(p\text{-}^t\text{Bu-C}_6\text{H}_4\text{N})_2\}$ and $\{\text{Ph}_2\text{P}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2\text{N})_2\}$.^{40,93} The synthesis of the later homoleptic cobalt complex is described below (Scheme 32).⁴⁰ The molecular structure of the homoleptic $[\{\text{Ph}_2\text{P}(p\text{-}^t\text{Bu-C}_6\text{H}_4\text{N})_2\}_2\text{Co}]$ and

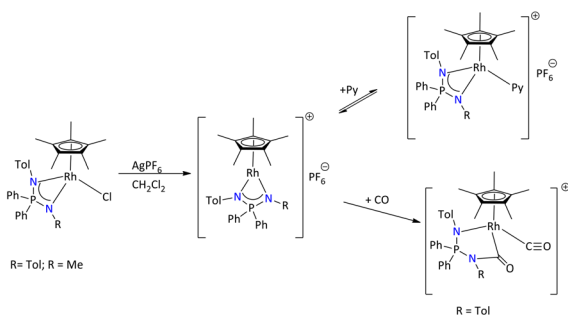

Scheme 32 Synthesis of the homoleptic Co(II) iminophosphonamide complex.⁴⁰

$[\{\text{Ph}_2\text{P}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2\text{N})_2\}_2\text{Co}]$ is isostructural, and suggests that the central Co(II) atom adopts a distorted tetrahedral geometry with dihedral angles of $82.7(2)^\circ$ and 88.01° , respectively, between two average CoN_2P planes.

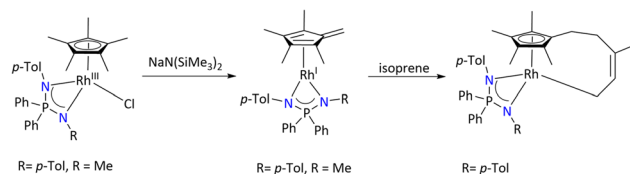

The four Co–N bond distances of these complexes are also in agreement with each other $[\{\text{Ph}_2\text{P}(p\text{-}^t\text{Bu-C}_6\text{H}_4\text{N})_2\}_2\text{Co}]$ (1.999–2.025 Å) and $[\{\text{Ph}_2\text{P}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2\text{N})_2\}_2\text{Co}]$ (2.015(1)–2.045(1) Å).

More recently, Kalsin's group has reported novel examples of structurally characterized half-sandwiched 18 VE and 16 VE rhodium iminophosphonamide complexes.⁹⁸ These complexes, $[\text{Cp}^*\text{RhX}\{\{\text{Ph}_2\text{P}(\text{N-R})(\text{N-R}')\}\}]$ ($\text{Cp}^* = \text{C}_5\text{Me}_5$; $\text{X} = \text{Cl}$; $\text{X} = \text{PF}_6$; $\text{R}, \text{R}' = p\text{-Tol}, p\text{-Tol}; p\text{-Tol}, \text{Me}$; and Me, Me) coordinated with either symmetric or non-symmetric iminophosphonamides (Scheme 33). Most of the half-sandwich rhodium complexes were synthesized in a similar way to the analogous ruthenium complexes.^{27,98} Furthermore, the reactivities of the cationic 16 VE rhodium complexes $[(\eta^5\text{-C}_5\text{Me}_5)\{\text{Ph}_2\text{P}(\text{N-}p\text{-Tol})(\text{NR})\}\text{Rh}]^+[\text{PF}_6]^-$ ($\text{R} = p\text{-Tol}$ and Me) were studied towards the reaction with pyridine and CO. The result indicated that due to the low coordination enthalpy of the pyridine adduct, it is stable only at low temperatures. In contrast when CO was reacted with the cationic complex, it resulted in the formation of a CO-inserted product.

Additionally, the fulvene complexes $[(\eta^4\text{-C}_5\text{Me}_4\text{CH}_2)\{\text{Ph}_2\text{P}(\text{N-}p\text{-Tol})(\text{NR})\}\text{Rh}]$ ($\text{R} = p\text{-Tol}$ and Me) were generated by the reaction of $[(\eta^5\text{-C}_5\text{Me}_5)\{\text{Ph}_2\text{P}(\text{N-}p\text{-Tol})(\text{NR})\}\text{RuCl}]$ ($\text{R} = p\text{-Tol}$ and Me) with $\text{NaN}(\text{SiMe}_3)_2$. Further the reaction of $[(\eta^4\text{-C}_5\text{Me}_4\text{CH}_2)\{\text{Ph}_2\text{P}(\text{N-}p\text{-Tol})(\text{NR})\}\text{Rh}]$ ($\text{R} = p\text{-Tol}$) with isoprene was carried out, which resulted in the formation of $[(\eta^5\text{-}\eta^1\text{-C}_5\text{Me}_4(\text{CH}_2)\text{C}(\text{Me})=\text{CHCH}_2)\text{Rh}\{\text{Ph}_2\text{P}(\text{N-}p\text{-Tol})_2\}]$, which was considered as

Scheme 33 Synthesis of the cationic half-sandwich rhodium complex and its reactivity.⁹⁸

Scheme 34 Synthesis of the fulvene rhodium complex and its reactivity with diene.⁹⁸

the first example of 1,4-metallacycloadaddition of diene to the fulvene complexes $[(\eta^4\text{-C}_5\text{Me}_4\text{CH}_2)\{\text{Ph}_2\text{P}(\text{N-}p\text{-Tol})(\text{NR})\}\text{Rh}]$ (Scheme 34).

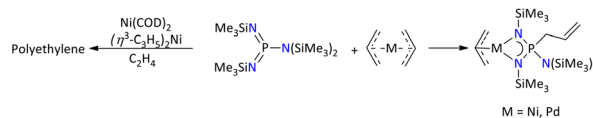

2.3.3 Syntheses of Ni, Pd and Pt complexes of iminophosphonamide. In 1981, Keim's group made a ground-breaking discovery by reporting the first-ever nickel and palladium complexes, $[(\eta^3\text{-C}_3\text{H}_5)\{\text{N}(\text{SiMe}_3)_2(\text{C}_3\text{H}_5)\text{P}(\text{N}(\text{SiMe}_3)_2)\}\text{M}]$ ($\text{M} = \text{Ni}$ and Pd), utilizing an iminophosphonamine ligand (Scheme 35).⁸²

During the formation of these compounds, bis(η^3 -allyl) Ni/Pd complexes underwent an unanticipated allyl rearrangement due to the iminophosphonamide ligand, which resulted in the production of a σ -bonded π -allyl group. These compounds acted as an active catalyst for the polymerization of ethylene at 70°C and 50 bar.

Later in 1985, Fink's group reported that the combination of the iminophosphonamide ligand and $[\text{Ni}(\text{COD})_2]$ or $[\text{Ni}(\eta^3\text{-C}_3\text{H}_5)_2]$ is a capable system for the polymerization of α -olefins into chains with variable methyl branching at low temperatures.⁹⁹

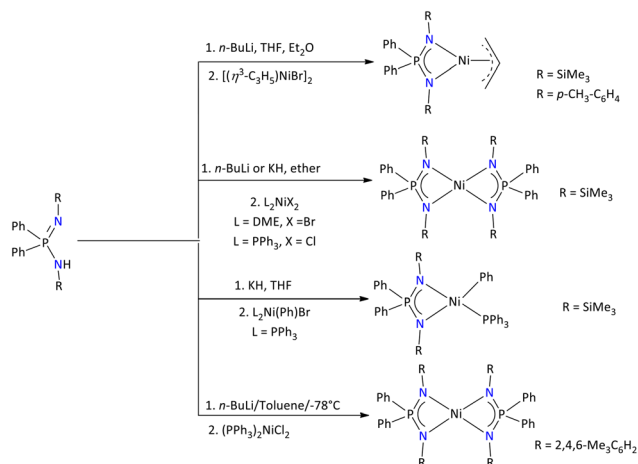

Collins' group has synthesized a variety of Ni iminophosphonamide complexes, as described in Scheme 36.¹⁰⁰

$[(\eta^3\text{-C}_3\text{H}_5)\{\text{Ph}_2\text{P}(\text{NR})_2\}\text{Ni}]$ ($\text{R} = \text{SiMe}_3$ and $p\text{-Tol}$) was synthesized by the reaction of *in situ* generated salt of the differently substituted $\{\text{Ph}_2\text{P}(\text{NR})_2\}$ ($\text{R} = \text{SiMe}_3$, 2,4,6-Me₃C₆H₂, $p\text{-Tol}$) ligands with $[(\eta^3\text{-C}_3\text{H}_5)\text{NiBr}]_2$. These complexes are stable in the open air for a short time. The NMR spectroscopy of these complexes revealed the non-fluxional behavior of the π -allyl group; however, through $\{\text{Ph}_2\text{P}(\text{NR})_2\}$ ligand reorientation, the chemical exchange could be observed. The molecular structure of these $[(\eta^3\text{-C}_3\text{H}_5)\{\text{Ph}_2\text{P}(\text{NR})_2\}\text{Ni}]$ complexes revealed the long Ni...N bond distance in the range of 1.941(1)–1.973(2) Å having an acute NPN bite angle with the ligand. When $[(\eta^3\text{-C}_3\text{H}_5)\{\text{Ph}_2\text{P}(\text{NR})_2\}\text{Ni}]$ was employed as a catalyst in the polymerization of ethylene, it resulted in no active catalysis. In search of an active catalyst, $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}\text{NiPh}(\text{PPh}_3)]$ was prepared from $[\text{NiPh}(\text{PPh}_3)_2\text{Br}]$ and *in situ* generated $\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}^-$ ligand. The complex is active for 1-hexene isomerization without any activator, and produces R-methyl styrene

Scheme 35 Syntheses of nickel and palladium iminophosphonamide complexes.^{82,99}

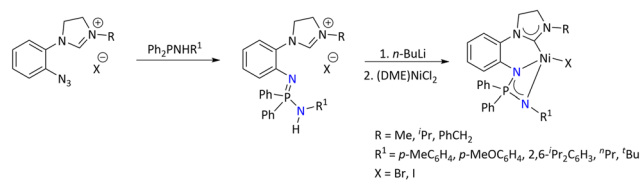

Scheme 36 Syntheses of discrete iminophosphonamide Ni(II) complexes.^{40,100}

when reacting with propene. However, it was observed that in the presence of suitable phosphine scavengers, $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}\text{NiPh}(\text{PPh}_3)]$ can polymerize ethylene. Furthermore, all these complexes are active towards the dimerization of ethylene in the presence of polymethylaluminumoxane (PMAO).

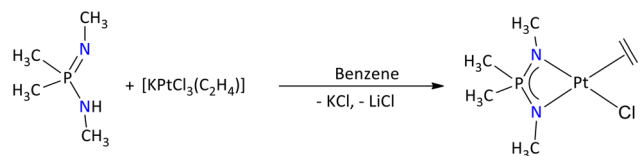

Various homoleptic Ni(II) complexes such as $[\{\text{Pr}_2\text{P}(\text{NMe})_2\}_2\text{Ni}]$, $[\{\text{Ph}_2\text{P}(2,4,6\text{-Me}_3\text{-C}_6\text{H}_2\text{N})_2\}_2\text{Ni}]$, and $[\{\text{Ph}_2\text{P}(\text{NPh})_2\}_2\text{Ni}]$ have also been reported and structurally characterized.^{40,101} In this regard, Singh's group reported the synthesis of homoleptic $[\{\text{Ph}_2\text{P}(2,4,6\text{-Me}_3\text{-C}_6\text{H}_2\text{N})_2\}_2\text{Ni}]$ by *in situ* deprotonation of the corresponding iminophosphonamine ligand followed by treatment with $[(\text{PPh}_3)_2\text{NiCl}_2]$ (Scheme 36). The characterization of the Ni(II) complex was further carried out by NMR spectroscopy and single-crystal X-ray diffraction. The ^1H NMR spectrum of the complex showed chemically non-equivalent protons of the *o*-methyl protons of the mesityl rings, which was attributed to the agostic interaction of the *o*-methyl protons with the Ni(II) centers. Furthermore, the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of the Ni(II) complex exhibited single resonance at -16.83 ppm, which is significantly upfield shifted as compared to the corresponding ligand (36 ppm). The non-equivalence nature of the *o*-methyl protons of the mesityl rings and agostic interaction was further confirmed by the molecular structure of the Ni(II) complex having a $\text{Ni}\cdots\text{H}$ distance of $2.673(1)$ Å.

Wang's group has reported various nickel iminophosphonamide complexes having a carbene substituent at the side arm.¹⁰² These complexes efficiently catalyzed cross-coupling reactions of Grignard reagents with aryl chlorides or fluorides (Scheme 37).

Zeise's salt analogue of the iminophosphonamide $[\{(\text{CH}_3)_2\text{P}(\text{NCH}_3)_2\}\text{PtCl}(\text{C}_2\text{H}_4)]$ was reported by Nahrstedt's group, by treating the lithium salt of the corresponding iminophosphonamine with $[\text{KPtCl}_3(\text{C}_2\text{H}_4)]$ in 2/1 molar ratio, respectively (Scheme 38).¹⁰³ The formation of the metal complex was confirmed and characterized by multinuclear NMR spectroscopy.

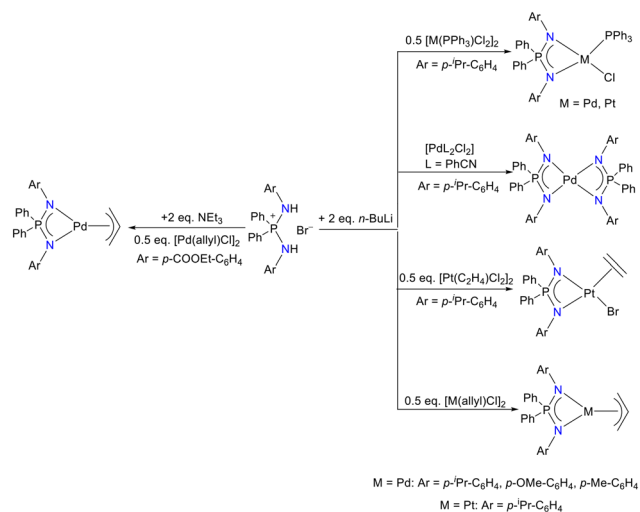

Scheme 37 Cross coupling using carbene-based Ni(II) iminophosphonamide complexes.¹⁰²

Scheme 38 Synthesis of Zeise's analogue iminophosphonamide ligand.¹⁰³

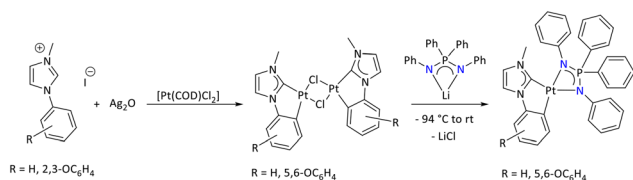

Ustynyuk and Kalsin's group reported various palladium and platinum complexes of the iminophosphonamide (Scheme 39).^{96,104} The structural analysis of these complexes was carried out by single-crystal X-ray diffraction. The results suggested an intramolecular weak $\text{C-H}\cdots\text{Pd}$ interaction in $[\{\text{Ph}_2\text{P}(p\text{-}^i\text{Pr-C}_6\text{H}_4\text{N})_2\}\text{Pd}(\text{PPh}_3)\text{Cl}]$ and an intermolecular weak $\text{C-H}\cdots\text{Pd}$ interaction in homoleptic $[\{\text{Ph}_2\text{P}(p\text{-}^i\text{Pr-C}_6\text{H}_4\text{N})_2\}\text{Pd}]$ complexes. It was observed that these weak interactions influenced the MNPN metallacycle planarity. The synthesized palladium complexes $[\{\text{Ph}_2\text{P}(p\text{-}^i\text{Pr-C}_6\text{H}_4\text{N})_2\}\text{Pd}(\text{PPh}_3)\text{Cl}]$ and $[\{\text{Ph}_2\text{P}(p\text{-COOEt-C}_6\text{H}_4\text{N})_2\}\text{Pd}(\eta^3\text{-allyl})]$ were also tested as catalysts in the Tsuji–Trost allylation and the Suzuki–Miyaura cross-coupling reactions.

More recently, Stassner's group reported the cyclometalated NHC Pt(II) complexes of iminophosphonamide (Scheme 40).¹⁰⁵ These complexes were synthesized by first treating the NHC

Scheme 39 Syntheses of palladium and platinum iminophosphonamide complexes.^{96,104}

Scheme 40 Synthesis of platinum iminophosphonamide complexes.¹⁰⁵

salt with Ag_2O , which resulted in the formation of silver carbene complexes. Further transmetalation of the silver(I) carbene complex with $[\text{Pt}(\text{COD})\text{Cl}_2]$ led to the formation of chloro bridged platinum complexes $[\{\text{C}^*\text{C}^*\}(\mu\text{-Cl})\text{Pt}]_2$ ($\text{C}^*\text{C}^* =$ cyclometalated N-heterocyclic carbene). Finally, a salt metathesis reaction with the *in situ* prepared lithium salt of the iminophosphonamide and chloro bridged platinum complexes yielded the expected platinum iminophosphonamide complexes $[\{\text{Ph}_2\text{P}(\text{NPh})_2\}(\text{C}^*\text{C}^*)\text{Pt}]$ after purification by neutral column chromatography.

The formation of complexes was confirmed by various techniques such as multinuclear NMR spectroscopy, elemental analysis, single-crystal X-ray diffraction and mass spectrometry as well. The ^{195}Pt NMR spectrum of the iminophosphonamide complex showed a signal at -3510 ppm ($\text{R} = \text{H}$) and -3483 ppm ($\text{R} = 5,6\text{-OC}_6\text{H}_4$), which is comparatively downfield shifted compared to the chloro bridged platinum complexes (-4050 ppm) in deuterated dimethyl sulfoxide.

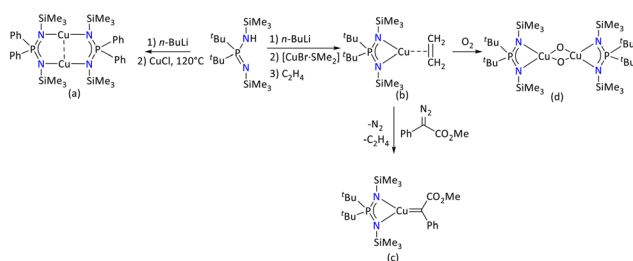

The molecular structure of the complex suggested that the nitrogen atoms of the ligand coordinated to the metal center with $79.37(7)^\circ$ NPtN bite angle ($\text{R} = \text{H}$). Furthermore, the NPtN and NPN planes are almost uniplanar with a slight deviation of 2.73° . The photophysical study of these complexes exhibited that depending on the NHC substituents, the emissive states of the Pt(II) complexes vary. The study of these complexes was examined by cyclic voltammetry (CV) and differential pulse voltammetry (DPV), and the results were supported by density functional theory (DFT).

2.3.4 Syntheses of Cu, Ag and Zn complexes of iminophosphonamide. In 1999, Hofmann's group reported a copper(I) olefin complex, $[\{\text{tBu}_2\text{P}(\text{NSiMe}_3)_2\}\text{Cu}(\text{C}_2\text{H}_4)]$, stabilized by a sterically demanding $\{\text{tBu}_2\text{P}(\text{NSiMe}_3)_2\}^-$ ligand (Scheme 41).¹⁰⁶ The stability of the Cu(I) olefin complex is due to the small N–

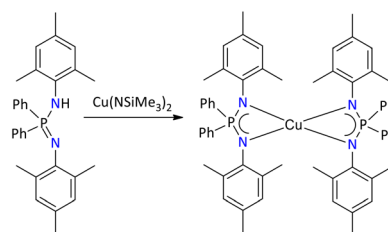

Cu–N bite angle ($77.80(9)^\circ$), which enhances the π -back bonding with the olefin and forms a strong dative bond with Cu(I). Using this copper(I) olefin complex, Hofmann's group was able to identify the Cu-carbene complex $[\{\text{tBu}_2\text{P}(\text{NSiMe}_3)_2\}\text{Cu}(\text{C}^*)\text{C}^*]$ that is important for catalytic cyclopropanation.⁸⁵ Furthermore, the reactivity of the Cu(I) olefin complex $[\{\text{tBu}_2\text{P}(\text{NSiMe}_3)_2\}\text{Cu}(\text{C}_2\text{H}_4)]$ has been reported towards O_2 gas, leading to the formation of a neutral butterfly bis(μ -oxo) copper(III) species.¹⁰⁷ Additionally, a salt metathesis reaction between CuCl and $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}\text{Li}]$ afforded the binuclear copper complex, $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}_2\text{Cu}_2]$.¹⁰⁸ The corresponding crystal structure shows that the two Cu(I) centers are linearly coordinated *via* a bridging coordination mode of the two iminophosphonamides. The Cu–Cu distance is 2.62 \AA , and thus, it is in the range of cuprophilic interactions.^{108,109}

Only one structurally characterized example of a Cu(II) iminophosphonamide complex has been reported and was accessed by the deprotonation of $\{\text{Ph}_2\text{P}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2\text{N})_2\}\text{H}$ with $[\text{Cu}\{\text{N}(\text{SiMe}_3)_2\}_2]$, resulting in the formation of the mononuclear homoleptic complex $[\{\text{Ph}_2\text{P}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2\text{N})_2\}_2\text{Cu}]$ (Scheme 42).⁴⁰

Bhoomishankar's group reported the silver complexes of pyridyl substituted iminophosphonamide.^{110,111} In this regard, treatment of $[\text{P}(\text{NHpy})_4]\text{Cl}$ with AgClO_4 led to the formation of a pentanuclear Ag(I) complex, $[\text{Ag}_5\{\text{P}(\text{Npy})_2(\text{NHpy})_2\}_2][\text{ClO}_4]_3$. Alternatively, this complex can also be synthesized by treating $[\text{P}(\text{NHpy})_4]\text{Cl}$ with a base first. This resulted in the formation of a neutral iminophosphonamine, $\text{P}(=\text{Npy})(\text{NHpy})_3$ ligand. Subsequent reaction with AgClO_4 also formed the pentanuclear Ag(I) complex $[\text{Ag}_5\{\text{P}(\text{Npy})_2(\text{NHpy})_2\}_2][\text{ClO}_4]_3$ (Scheme 43). The five-fold positive charge due to five Ag(I) ions in the cluster is stabilized by two anionic iminophosphonamide ligands and three perchlorate anions. Both ligands functioned as hexadentate donor ligands. The molecular structure of the metal complex revealed that the intermetallic Ag...Ag interaction lies in the range from $2.9647(7) \text{ \AA}$ to $3.1772(12) \text{ \AA}$ and is comparable with the literature.¹¹² Additionally another Ag(I) complex, $[\text{Ag}_5\{\text{P}(\text{Npy})_2(\text{NHpy})_2\}_2][\text{OTf}]_3$, was synthesized by reacting $[\text{P}(\text{NHpy})_4]\text{Cl}$ with the more reactive silver triflate $\text{Ag}(\text{OTf})$. In both compounds, the same cation, $[\text{Ag}_5\{\text{P}(\text{Npy})_2(\text{NHpy})_2\}_2]^+$, suggested the thermodynamic stability of the pentanuclear Ag(I) complex with different counter anions.

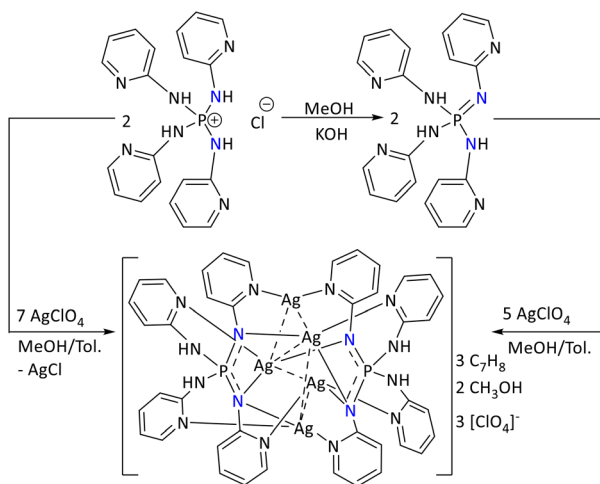

Scheme 41 Iminophosphonamide-supported (a) copper(I) binuclear copper complex, (b) olefin-copper(I) complex, (c) copper(I) carbene and (d) bis(μ -oxo) copper(III) species.^{106–108}

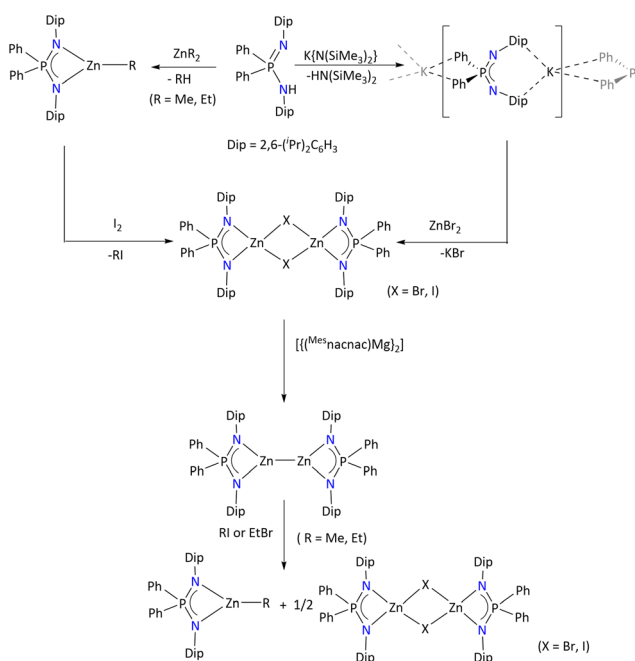

Scheme 42 Synthesis of iminophosphonamide-supported homoleptic copper(II) complex.⁴⁰

Scheme 43 Synthesis of silver(I) iminophosphonamide complexes.^{110,111}

To the best of our knowledge, divalent zinc complexes have only been obtained by using $\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}$ ³⁹ and $\{\text{Py}_2\text{P}(\text{Me}_3\text{SiN})_2\}$ ^{148,113} as non-chiral ligands. In this regard, Stasch's group has demonstrated that a monovalent zinc complex could be stabilized by the sterically demanding $\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}$ ligand (Scheme 44). As shown, the heteroleptic zinc complex $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{Zn}(\mu\text{-X})_2\text{Zn}\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}]$ can be obtained either by salt metathesis between the potassium salt of the ligand and ZnBr_2 or by reacting the pre-synthesized heteroleptic complex $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{ZnR}]$ with I_2 . Further, the single electron

Scheme 44 Syntheses of Zn(I) and Zn(II) iminophosphonamide complexes.

reduction of $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{Zn}(\mu\text{-X})_2\text{Zn}\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}]$ by $[\{(\text{Mes})\text{nacnac}\}\text{Mg}\}_2]$ afforded the monovalent zinc complex $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{Zn}]_2$. The intermetallic Zn–Zn distance is 2.3132(9) Å, which is consistent with previously known dimeric Zn(I) species.

The ¹H NMR spectrum of $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{Zn}]_2$ shows the absence of a $[\{\text{Ph}_2\text{P}(2,6\text{-}i\text{Pr}_2\text{C}_6\text{H}_3\text{N})_2\}\text{ZnH}]$ species, which further support the presence of a Zn–Zn bond in the complex. Moreover, the reactivity of this Zn(I) complex was explored towards small molecules such as RI (R = Me and Et) or EtBr, which resulted in the umpolung of the alkyl halides.

2.4 f-Block metal complexes based on iminophosphonamides

Compared to the well-researched amidinate chemistry of rare earth metals, there has been relatively little investigation into the related coordination chemistry with iminophosphonamides. Most contributions since the 1990s have come from the field's pioneers, Edelmann and Schumann.^{39,114–116} In these early reports, ligands consisting of silyl, aryl, and alkyl-substituted N-centers of various iminophosphonamide complexes have been generally used in rare earth metal chemistry (Fig. 5).¹¹⁷

The early reports of lanthanide iminophosphonamide metal complexes are based on silyl-substituent (**I**, Fig. 5). In particular, Edelmann's group reported and structurally characterized the Sm(III) and Yb(II) complexes $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}_2\text{Sm}(\mu\text{-I}_2)\text{Li}(\text{thf})_2]$ and $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}_2\text{Yb}(\text{thf})_2]$ bearing the same iminophosphonamide ligand in 1991 (Scheme 45).¹¹⁶ Furthermore, Edelmann's group reported in 1995, a series of $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}_2\text{Ln-COT}]$ (COT = cyclooctatetraene) (Ln = Ce, Pr, Nd, and Sm) complexes bearing the same ligand

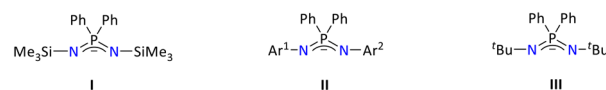

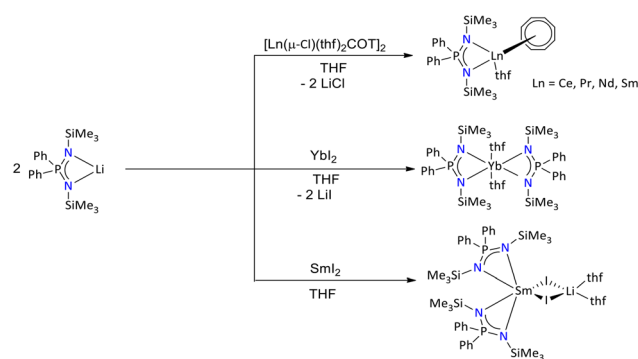

Fig. 5 Iminophosphonamide ligands used in rare earth metal complexes.¹¹⁷

Scheme 45 Syntheses of silyl-substituted iminophosphonamide complexes of lanthanides.^{115,116}

(Scheme 45).¹¹⁵ These complexes were obtained by salt metathesis of $[\{\text{Ph}_2\text{P}(\text{NSiMe}_3)_2\}\text{Li}]$ and $[\text{Ln}(\mu\text{-Cl})(\text{thf})_2\text{COT}]_2$.

Most of the alkyl and aryl substituted iminophosphonamide lanthanide complexes were used as catalysts for the polymerization of olefins.^{118–121} In this regard, in 2010, Cui and co-workers demonstrated that selective isoprene polymerization could be achieved when different lanthanide metal complexes were employed as catalysts (Scheme 46). The bis(alkyl)iminophosphonamide complex of lutetium, $[\text{Ph}_2\text{P}\{(2\text{-pyridyl-N})(=\text{NC}_6\text{H}_4\text{Me}_2)\}(\text{thf})\text{Lu}(\text{CH}_2\text{SiMe}_3)_2]$, was synthesized by the deprotonation reaction of the iminophosphonamine $\text{Ph}_2\text{P}\{(2\text{-pyridyl-NH})(=\text{NC}_6\text{H}_4\text{Me}_2)\}$ with $[\text{Lu}(\text{CH}_2\text{SiMe}_3)_3(\text{thf})_2]$. Furthermore, when the $\text{Ph}_2\text{P}\{(2\text{-pyridyl-NH})(=\text{NC}_6\text{H}_4\text{Me}_2)\}$ ligand was reacted with $[\text{Nd}(\text{BH}_4)_3(\text{thf})_3]$, an unprecedented reaction occurred leading to the formation of a bis(borohydride) neodymium complex. The synthesized lutetium complex $[\text{Ph}_2\text{P}\{(2\text{-pyridyl-N})(=\text{NC}_6\text{H}_4\text{Me}_2)\}(\text{thf})\text{Lu}(\text{CH}_2\text{SiMe}_3)_2]$ in combination with proper cocatalysts $[\text{PhMe}_2\text{NH}][\text{B}(\text{C}_6\text{F}_5)_4]$ and Al^iBu_3 afforded the 3,4 selectivity, whereas the neodymium borohydride complex selectively afforded the *trans*-1,4 product in the presence of $[\text{PhMe}_2\text{NH}][\text{B}(\text{C}_6\text{F}_5)_4]$ and Mg^nBu_2 .¹²⁰

Cui's group in 2014, also reported the dialkyl complexes of lutetium ligated with variably substituted iminophosphonamide of type **II** (Fig. 5 and Scheme 47). The structural determination of these complexes was carried out by various spectroscopic techniques including single-crystal X-ray diffraction.

These complexes were tested as catalysts in the polymerization of isoprene. The result indicated that all these complexes appeared as effective 3,4 regioselective catalysts. Depending on the ligand substituent, the syndio- and iso-3,4 selectivity of the isoprene polymerization was observed, which was supported by DFT calculations.¹¹⁸

Furthermore, a series of bis(alkyl) complexes $[\{\text{Ph}_2\text{P}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2\text{N})(\text{NAr})\}\text{Ln}(\text{CH}_2\text{SiMe}_3)_2(\text{thf})_2]$ ($\text{Ln} = \text{Lu}, \text{Y}, \text{Sc}, \text{and Er}$; $\text{Ar} = \text{Ph}$ and 2-pyridyl) were generated and structurally charac-

terized.¹¹⁹ These complexes were tested for isoprene polymerization in the presence of $[\text{Ph}_3\text{C}][\text{B}(\text{C}_6\text{F}_5)_4]$ and Al^iBu_3 .

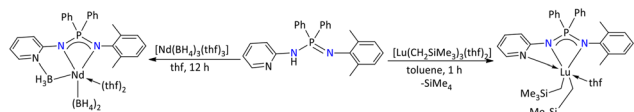

Research on the catalytic polymerization of isoprene by Cui revealed that the substituents on the nitrogen atoms and the atomic radii of the corresponding central metal atoms determine the catalytic activity and selectivity.¹²² Furthermore, it was investigated how the molecular architectures of the complexes and their catalytic capabilities correlate.

The study on regio- and stereoselective isoprene polymerization was further carried out using dialkyl lanthanide complexes of iminophosphonamide $[\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{PrC}_6\text{H}_3\text{N})_2\}\text{Ln}(\text{R})_2(\text{thf})]$ ($\text{Ln} = \text{Sc}, \text{Lu}, \text{Y}, \text{and Er}$; $\text{R} = \text{CH}_2\text{SiMe}_3$ and for $\text{Ln} = \text{La}$ and Nd ; $\text{R} = \text{CH}_2\text{-}p\text{-Tol}$) as catalysts in the presence of activator systems $[\text{Ph}_3\text{C}][\text{B}(\text{C}_6\text{F}_5)_4]/\text{Al}^i\text{Bu}_3$ and $[\text{Ph}_3\text{C}][\text{B}(\text{C}_6\text{F}_5)_4]/\text{AlEt}_3$, respectively. The study found that the lanthanide complexes, $[\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{PrC}_6\text{H}_3\text{N})_2\}\text{Ln}(\text{CH}_2\text{SiMe}_3)_2(\text{thf})]$ ($\text{Ln} = \text{Sc}, \text{Lu}, \text{Y}, \text{and Er}$) with a smaller ionic size in the presence of $[\text{Ph}_3\text{C}][\text{B}(\text{C}_6\text{F}_5)_4]/\text{Al}^i\text{Bu}_3$ tend to favor a high 3,4-regio and stereoselectivity for the polymerization of isoprene (up to 98.1%). While the 4-methylbenzyl neodymium and lanthanum complexes $[\{\text{Ph}_2\text{P}(2,6\text{-}^i\text{PrC}_6\text{H}_3\text{N})_2\}\text{Ln}(\text{CH}_2\text{-}p\text{-Tol})_2(\text{thf})]$ ($\text{Ln} = \text{La}$ and Nd) in the presence of $[\text{Ph}_3\text{C}][\text{B}(\text{C}_6\text{F}_5)_4]/\text{AlEt}_3$ demonstrated efficient catalytic activity in the *trans*-1,4-selective polymerization of isoprene (Scheme 48).^{123,124}

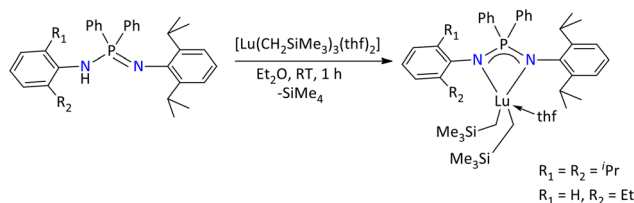

Of the three above-described NPN ligand backbone types, Sundermeyer's group initially introduced the $\{\text{Ph}_2\text{P}(\text{N}^i\text{Bu})_2\}$ ligand (Fig. 5, **III**) into the rare earth metal chemistry in 2016.¹¹⁷ For instance, dialkyl or monoalkyl substituted rare earth metal (Sc and Y) complexes of $\{\text{Ph}_2\text{P}(\text{N}^i\text{Bu})_2\}$ can be synthesized by reacting the iminophosphonamine with $[\text{Ln}(\text{CH}_2\text{SiMe}_3)_3(\text{thf})_3]$ in an appropriate ratio (Scheme 49).

Alternatively, $\{\text{Ph}_2\text{P}(\text{N}^i\text{Bu})_2\}\text{H}$ was reacted with ScCl_3 and MeLi to give $[\{\text{Ph}_2\text{P}(\text{N}^i\text{Bu})_2\}_2\text{Sc}(\text{Me})\text{thf}]$ (Scheme 49).

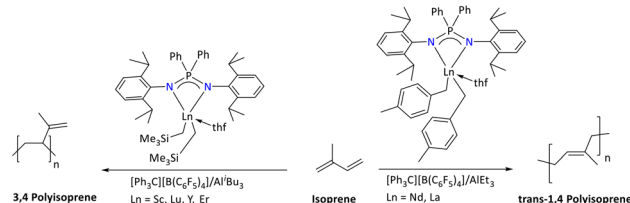

Moreover, the mono-alkyl substituted complexes are reactive towards the abstraction of acidic $-\text{CH}$ protons (Scheme 50).¹¹⁷ In this regard, an *in situ* prepared yttrium mono alkyl $[\{\text{Ph}_2\text{P}(\text{N}^i\text{Bu})_2\}_2\text{Y}(\text{CH}_2\text{SiMe}_3)]$ complex when treated with phenylacetylene resulted in the formation of a highly air- and moisture-sensitive colorless yttrium alkyne complex. The formation of the alkynyl complex was confirmed by multinuclear NMR spectroscopy. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectra of the yttrium alkynyl $[\{\text{Ph}_2\text{P}(\text{N}^i\text{Bu})_2\}_2\text{Y}(\text{C}\equiv\text{CPh})]$ complex exhibited a single resonance at $\delta = 17.8$ ppm upfield shifted compared to the monoalkyl yttrium complex ($\delta = 19.5$ ppm). Furthermore, the reaction of $[\{\text{Ph}_2\text{P}(\text{N}^i\text{Bu})_2\}_2\text{Y}(\text{CH}_2\text{SiMe}_3)]$ with $[\text{PhNHMe}_2][\text{B}$

$(C_6F_5)_4$ afforded the cationic yttrium complex $[Y(Ph_2P(NHPh)P(Ph)_2)_2]^+ [B(C_6F_5)_4]^-$. The formation of the cationic complex was confirmed by NMR spectroscopy, which displayed signals corresponding to $PhNMe_2$ and $SiMe_4$. The other characteristic signals in the multinuclear NMR spectra were also consistent with the product formation.¹¹⁷

More recently, Konchenko's group reported a variety of trisiminophosphonamide lanthanide complexes utilizing chromophore 2-(phen-2'-yl)-1,3-benzothiazole (Pbt) substituents at the nitrogen centers of the iminophosphonamine, $Ph_2P(HNPbt)(NPbt)$.¹²⁵

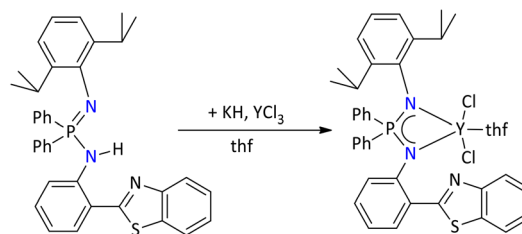

The corresponding iminophosphonamide lanthanide complexes were synthesized by a salt metathesis between $LnCl_3$ and *in situ* generated $K\{Ph_2P(NPbt)_2\}$ regardless of the stoichiometry of the precursors. In all cases, $[Ln\{Ph_2P(NPbt)_2\}_2]^+$ ($Ln = Y, Sm, Gd, \text{ and } Dy$), where $[Ln\{Ph_2P(NPbt)_2\}_2]^+$ exists as cationic fragment and $[Ph_2P(NPbt)_2]^-$ as its counter anion, were isolated (Scheme 51). Furthermore, the photoluminescence of $Ph_2P(HNPbt)(NPbt)$ showed two emission bands in the visible range, suggesting the relationship between the color of luminescence and the excitation wavelength. In contrast, only a single band was observed when the photoluminescence was measured in solution. This peculiar observation is conditioned to the specific effect of packing in the solid state of the ligand. Furthermore, the potassium salt $K\{Ph_2P(NPbt)_2\}$, $[Gd\{Ph_2P(NPbt)_2\}_2][Ph_2P(NPbt)_2]$ and $[Dy\{Ph_2P(NPbt)_2\}_2][Ph_2P(NPbt)_2]$,

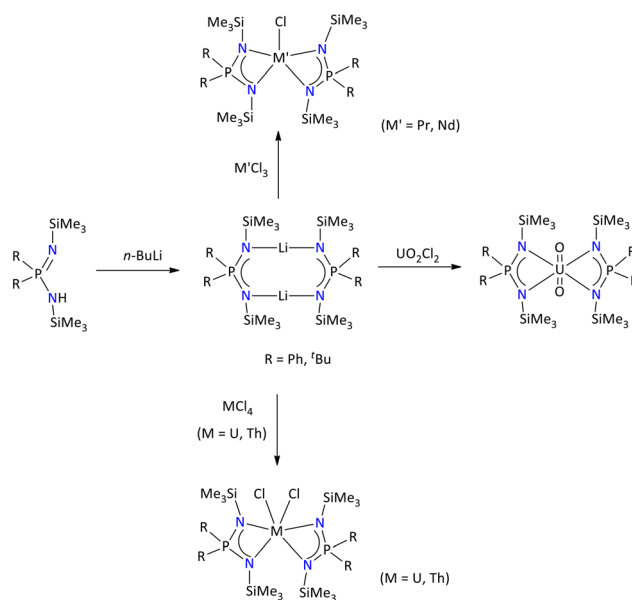

Scheme 51 Synthesis of luminescent lanthanide complexes.¹²⁵

when excited, showed bright emission bands of different colors depending on the metal center, both in solution and in the solid state.

More recently, Konchenko's group reported the yttrium complex using a nonsymmetric benzothiazole-functionalized iminophosphonamide ligand. The yttrium complex was synthesized by *in situ* deprotonation of iminophosphonamine with potassium hydride followed by a reaction of yttrium trichlorides in THF (Scheme 52). The molecular structure of the protonated ligand and yttrium complex showed that there is intermolecular π -stacking between the 2-(phen-2'-yl)-1,3-benzothiazole (Pbt) fragments.¹²⁶ Edelmann's group reported both lanthanide and actinide iminophosphonamide metal complexes ($M = Nd, Pr, Th, \text{ and } U$) by reacting $[Y(Ph_2P(NSiMe_3)_2)_2Li(thf)_2]$ with anhydrous chlorides of lanthanide and actinides (Scheme 53).¹¹⁴ The formation of these metal complexes was accessed through multinuclear NMR spectroscopy, elemental analysis, and mass spectrometry. The $^{31}P\{^1H\}$ NMR spectrum of the thorium complex, $[Y(Ph_2P(NSiMe_3)_2)_2ThCl_2]$, and the dioxouranium complex, $[Y(Ph_2P(NSiMe_3)_2)_2UO_2]$, displayed a single resonance in the positive region at $\delta = 17.4$ ppm and $\delta =$

Scheme 52 Synthesis of a luminescent yttrium complex.¹²⁶

Scheme 53 Syntheses of lanthanide and actinide iminophosphonamide complexes.¹¹⁴

42.9 ppm, respectively, while the rest of the metal complexes exhibited a single peak in the negative region ranging from -231.3 ppm to -139.6 ppm.

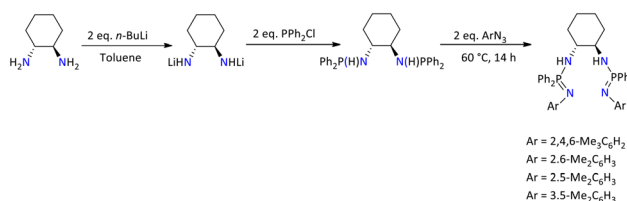

3 Enantiopure iminophosphonamide metal complexes

As discussed in the above sections, the coordination chemistry dealing with nonchiral iminophosphonamide is well explored. In contrast to this, few reports of chiral iminophosphonamide are known in the literature.

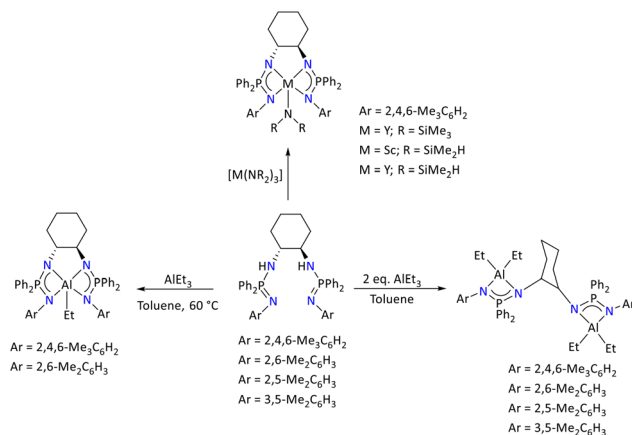

In this context, Hill's group reported the DACH (DACH = *trans*-1,2-diaminocyclohexane) bis(iminophosphonamide)-bridged ligands in 2007.¹²¹ The DACH substituted ligands were synthesized by deprotonating the *trans*-1,2-diaminocyclohexane with 2 eq. of *n*-BuLi in toluene, first. Subsequent reaction with 2 eq. of $\text{Ph}_2\text{P}(\text{H})\text{Cl}$ resulted in an exothermic reaction due to precipitation of LiCl . Further reaction with the appropriate azide afforded *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{HNP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2$] (Scheme 54). The ^1H NMR spectrum of the ligands exhibited the expected signals including the *NH* resonances; additionally, the purity was confirmed by the appearance of single signals in their corresponding $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum. This variably substituted *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{HNP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2$] iminophosphonamide at one of the nitrogen atoms was treated with 1 eq. of triethyl aluminum. This led to the formation of the monometallic aluminum complex *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{NP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2\text{AlEt}$] having a N_4 chelate, whereas when the ligand was treated with 2 eq. of AlEt_3 it furnished the bimetallic aluminum complex having N_2 chelates.

Similarly, when the ligands *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{HNP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2$] were reacted with $[\text{M}(\text{NR}_2)_3]$ ($\text{M} = \text{Y}$ and Sc ; $\text{R} = \text{SiMe}_3$ and SiHMe_2), it resulted in the formation of the N_4 chelates of $\text{M} = \text{Y}$ and Sc (Scheme 55). The bimetallic aluminum complexes *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{NP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2(\text{AlEt}_2)_2$] ($\text{Ar} = 2,4,6\text{-Me}_3\text{C}_6\text{H}_2$, $2,6\text{-Me}_2\text{C}_6\text{H}_3$) displayed the single resonances in the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum in a very narrow range (*i.e.*, 34 ppm to 37 ppm), suggesting the symmetric coordination environment around the metal centers.

In contrast, the $^{31}\text{P}\{^1\text{H}\}$ monometallic aluminum complex *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{NP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2\text{AlEt}$] ($\text{Ar} = 2,4,6\text{-Me}_3\text{C}_6\text{H}_2$ and $2,6\text{-Me}_2\text{C}_6\text{H}_3$) exhibited two peaks with an equal integral ratio based on integration. These signals were assigned by the Karplus relationship with the axial cyclohexane protons.

Scheme 54 Synthetic route for *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{HNP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2$].¹²¹

Scheme 55 Syntheses of metal ($\text{M} = \text{Al}$, Sc , and Y) complexes of *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{HNP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2$].¹²¹

Further, these monometallic and bimetallic complexes were employed as catalysts for methylmethacrylate (MMA) polymerization at room temperature. The results showed that both mono metallic *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{NP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2\text{AlEt}$] ($\text{Ar} = 2,4,6\text{-Me}_3\text{C}_6\text{H}_2$ and $2,6\text{-Me}_2\text{C}_6\text{H}_3$) and bimetallic aluminum complexes, *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{NP}(\text{Ph}_2)\text{N}(\text{Ar})\}_2(\text{AlEt}_2)_2$] ($\text{Ar} = 2,4,6\text{-Me}_3\text{C}_6\text{H}_2$ and $2,6\text{-Me}_2\text{C}_6\text{H}_3$), require three-component Gibson initiators,¹²⁷ ($\text{L}_2\text{AlR}/\text{MAD}/\text{Ni}(\text{acac})_2$) ($\text{MAD} = \text{bis}(2,6\text{-di-}t\text{-butyl-4-methylphenoxide})\text{aluminum methyl}$) for active polymerization to yield a syndiotactic ($>80\%$) pattern with broad polydispersity indices (~ 2). In contrast, efficient catalysis with a mostly isotactic ($>80\%$) pattern close to monodisperse was observed when the yttrium complexes, *rac*-[*trans*-1,2- $\text{C}_6\text{H}_{12}\{\text{NP}(\text{Ph}_2)\text{N}(2,4,6\text{-Me}_3\text{C}_6\text{H}_2)\}_2\text{Y}(\text{NR}_2)$] ($\text{R} = \text{SiMe}_3$ and SiHMe_2), were employed as catalysts.

Later in 2017, Guan's group has reported a variety of functionalized chiral iminophosphonamines, where the chiral centers were present at one nitrogen atom of the diamines (*i.e.*, (1*R*,2*R*)-diaminocyclohexane or (1*R*,2*R*)-diphenylethylenediamine) (Fig. 6).¹²⁸

Further metal complexation of these ligands was accessed by treating the ligands with metal benzyl compounds of alkaline earth and rare earth metals (Scheme 56).

The ^1H NMR spectra of the metal complexes confirmed complete deprotonation of the ligand. Further, the synthesized metal alkyl complexes bearing chiral iminophosphonamines were investigated as catalysts in the cross-dehydrogenative coupling of amines with prochiral silanes. The best catalytic activity was observed with the yttrium complex bearing a 1,2-

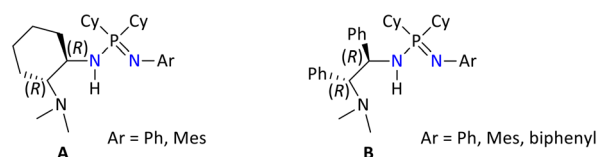

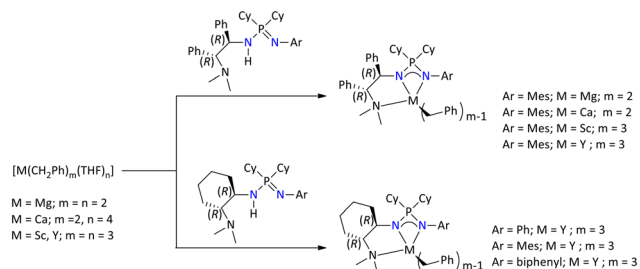

Fig. 6 Variably substituted chiral iminophosphonamines.

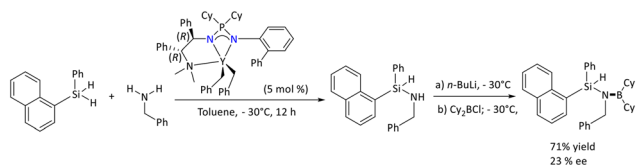

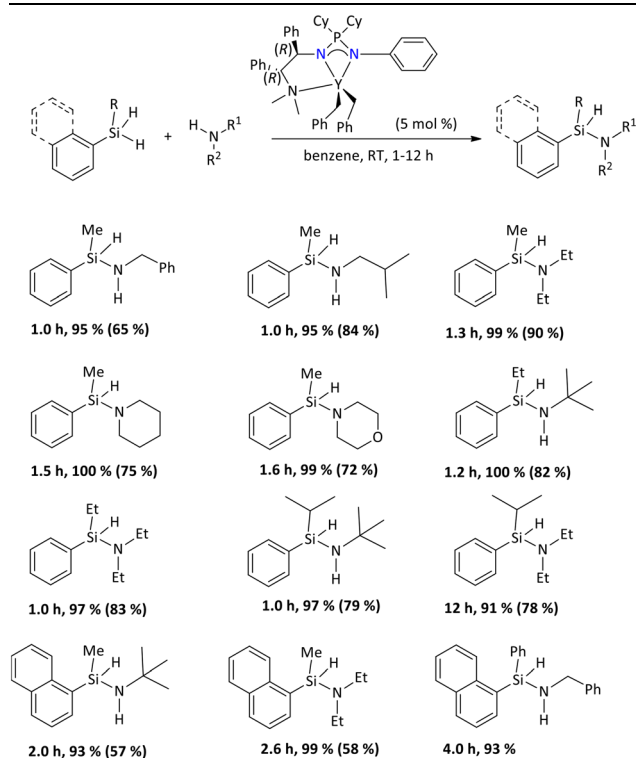

Scheme 56 Syntheses of alkaline and rare earth metal complexes of chiral iminophosphonamines.¹²⁸

diphenyl ethylenediamine moiety compared to the one with a 1,2-diamino cyclohexane moiety. This catalyst was further subjected to broad substrates of amine and prochiral silane, which showed excellent yield of the silylamines (Table 1).¹²⁸ All of the isolated silylamines were found to have a negative specific optical rotation.

Due to the high moisture sensitivity of the isolated silylamines, the conventional chiral HPLC method to determine ee was unsuccessful. Therefore, to assess the ee of silylamines, the stable derivative of silylamines was isolated. In this regard, the silylamine-boron derivative was synthesized by direct deprotonation/boronation in a single pot (Scheme 57). The resulting chiral silylamine boron derivative was analyzed using chiral HPLC, which exhibited the best catalytic activity having

Table 1 Substrate scope for the catalytic formation of silylamines; the yield was recorded by ¹H NMR spectroscopy and the values in the bracket are isolated yields¹²⁸

Scheme 57 Asymmetric chiral silamine catalysis using the yttrium benzyl complex.¹²⁸

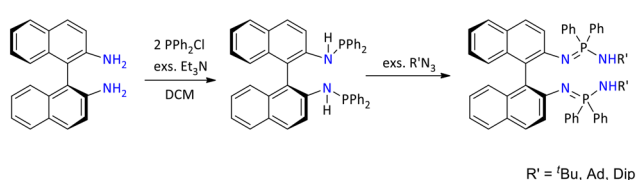

71% isolated yield and 23% ee when the yttrium complex bearing 1,2-diphenyl ethylenediamine at one end and biphenyl substituent at another nitrogen end of the iminophosphonamide was employed as the catalyst.

Further in 2019, Rufanov's group reported various *C*₂-symmetric bis(iminophosphonamide) ligands.³³ These ligands were synthesized by reacting the (*R*)-1,1'-binaphthyl-2,2'-diamine {(*R*)-Binam} with Ph₂PCl with Et₃N in DCM, resulting in the formation of (*R*)-*N,N'*-bis(diphenylphosphanyl)-2,2'-diamino-1,1'-binaphthyl [(*R*)-Binam-P]. Further, the Staudinger reaction was performed between the (*R*)-Binam-P and R'-N₃ (R' = ^tBu, Dip, and 1-Ad), which resulted in a series of *C*₂-symmetric bis(iminophosphonamide) ligands [(*R*)-Binam(Ph₂PN(H)R')₂] (R' = ^tBu, Ad and Dip) (Scheme 58). The ligands were characterized by multinuclear NMR (¹H, ³¹P, ¹³C) spectroscopy, EI-MS and elemental analysis, whereas the molecular structure of [(*R*)-Binam(Ph₂PN(H)^tBu)₂] was determined by growing suitable crystals for X-ray diffraction in a concentrated solution of [(*R*)-Binam(Ph₂PN(H)^tBu)₂] in DMSO. The ligand crystallized with 2 molecules of DMSO, forming N-H...O hydrogen bonds with the DMSO molecules.

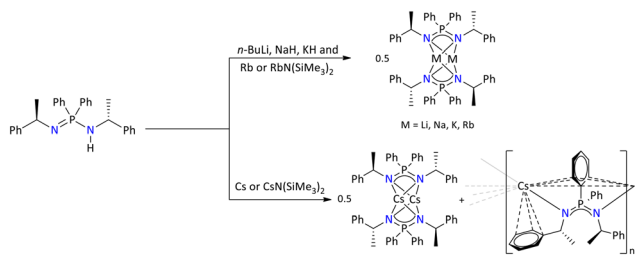

To the best of our knowledge, the coordination chemistry of the [(*R*)-Binam(Ph₂PN(H)R')₂] is yet unknown.

In contrast to the above-described chiral iminophosphonamines, where chirality was close to one nitrogen atom, the chirality centers close to both nitrogen atoms of the iminophosphonamines were largely uncommon. In this regard, P. Roesky's group reported in 2019 that the [Ph₂P{N(*R*)CH(CH₃)Ph}₂] ligand has chiral centers at both ends of the ligand.¹²⁹ The ligand was synthesized by performing a Staudinger reaction between (*R*)-α-methylbenzyl azide and HN(*R*-CHMePh)(PPh₂). The constitution of the ligand was confirmed by NMR spectroscopy, IR spectroscopy, and elemental analysis, and its molecular structure was accessed by single-crystal X-ray diffraction.

When the ligand [Ph₂P{HN(*R*)CH(CH₃)Ph}{N(*R*)CH(CH₃)Ph}] was deprotonated with appropriate alkali metal bases, it

Scheme 58 Synthesis of *C*₂-symmetric bis(iminophosphonamide) ligands.³³

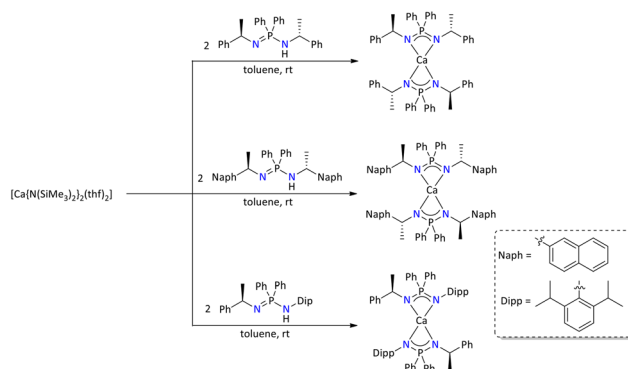

Scheme 59 Syntheses of alkali metal complexes of $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}]_2$.¹²⁹

resulted in the formation of dimeric metal complexes, $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\text{M}]_2$ [$\text{M} = \text{Li}, \text{Na}, \text{K}$, and Rb]. Interestingly, when the ligand was treated with cesium precursors, it formed dimeric $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\text{Cs}_2]$ and 1D-polymeric $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}\text{Cs}]_n$ species in 1/1 ratio (Scheme 59). Complete deprotonation of the ligand was confirmed by the disappearance of the NH signal in the ^1H NMR spectrum of the metal complexes. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectra of all these metal complexes also exhibited single resonances in the range from $\delta = 12.6$ to $\delta = 20.6$ ppm, which is downfield shifted as compared to the ligand $[\text{Ph}_2\text{P}\{\text{HN}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}]$ ($\delta = 2.7$ ppm). Moreover, the molecular structures of these metal complexes were confirmed by X-ray diffraction, which revealed that the cesium complex adopts both dimeric and polymeric forms, whereas the rest of the metal complexes exist in dimeric forms. The photoluminescence (PL) investigations at variable temperatures of the ligand $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}]_2$ and all its alkali metal complexes $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}\text{M}]_2$ [$\text{M} = \text{Li}, \text{Na}, \text{K}, \text{Rb}$, and Cs] revealed that the ligand is fluorescent in nature at all temperatures. In contrast, the alkali metal complexes showed phosphorescence at low temperatures (<100 K) and thermally activated delayed fluorescence (TADF) above ~ 150 K with a PL quantum efficiency of up to 36% for $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\text{Na}]_2$.

DFT calculations revealed the small S_1/T_1 energy gap for all the alkali metal complexes; further, the effective intersystem crossing S_1/T_1 energy states was due to the dimeric forms of these metal complexes.¹²⁹

To understand the effect of the ligand substituent on the photophysical properties of the metal complexes, symmetrically $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2]$, $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{naph}\}_2]$ (naph = naphthyl)- and non-symmetrically $[\text{Ph}_2\text{P}\{\text{NDipp}\}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}]$ (Dipp = 2,6- $i\text{Pr}_2\text{C}_6\text{H}_3$)-substituted chiral iminophosphonamides were synthesized. The new symmetric ligand $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{naph}\}_2]$ and the non-symmetric $[\text{Ph}_2\text{P}\{\text{NDipp}\}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}]$ ligand were obtained by reacting the iminophosphorane with corresponding azides.¹³⁰

Performing transamination between the $[\text{Ca}\{\text{N}(\text{SiMe}_3)_2\}(\text{thf})_2]$ and above-mentioned symmetric and non-symmetric ligands afforded the homoleptic calcium complexes, $[\{\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\}_2\text{Ca}]$, $[\{\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{naph}\}_2\}_2\text{Ca}]$ and $[\{\text{Ph}_2\text{P}\{\text{NDipp}\}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\}_2\text{Ca}]$ (Scheme 60). The PL study of these metal complexes in solid state at various temp-

Scheme 60 Syntheses of chiral homoleptic calcium complexes.¹³⁰

eratures exhibited blue green PL. The emission of $[\{\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{naph}\}_2\}_2\text{Ca}]$ was assigned to the fluorescence of naphthyl rings, whereas the emission of complexes $[\{\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\}_2\text{Ca}]$ and $[\{\text{Ph}_2\text{P}\{\text{NDipp}\}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\}_2\text{Ca}]$ exhibited phosphorescence at low temperatures and TADF at elevated temperatures. Different PL lifetimes suggested that the ligand substituents played a vital role in the PL of these calcium complexes. Moreover, all these homoleptic calcium complexes showed excellent catalytic activity in the hydroboration of ketones at room temperature.¹³⁰ Further the coordination chemistry of the $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2]$ ligand was explored with group 13 metal centers.¹³¹ In this regard, when the ligand was treated with LiAlH_4 , it resulted in the formation of $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\text{AlH}]$. Treating the lithium salt of the ligand $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}\text{Li}]_2$ with MCl_3 ($\text{M} = \text{Al}$ and Ga) resulted in the formation of corresponding monochloride complexes $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\text{MCl}]$ ($\text{M} = \text{Al}$ and Ga). Moreover, the halide abstraction of the monochloride complexes afforded corresponding tetracoordinated cationic complexes $[\{\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\}_2\text{Al}]^+[\text{GaCl}_4]^-$ and $[\{\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2\}_2\text{Ga}]^+[\text{AlCl}_4]^-$ (Fig. 7).

All these complexes were thoroughly characterized by multinuclear NMR and IR spectroscopy, elemental analysis, and X-ray diffraction.¹³¹

The effect of substituent variation in the iminophosphonamide metal complexes on photoluminescence (PL) was further investigated with d^{10} configured metal centers. In this regard, various $\text{Cu}(\text{I})$ and $\text{Zn}(\text{II})$ metal complexes of iminophosphonamides were synthesized (Scheme 61). The binuclear $\text{Cu}(\text{I})$ complexes $[\text{Ph}_2\text{P}\{(\text{NR})(\text{NR}')\}_2\text{Cu}_2]$ ($\text{R} = \text{R}' = (\text{R})\text{CH}(\text{CH}_3)\text{Ph}$ and $\text{R} =$

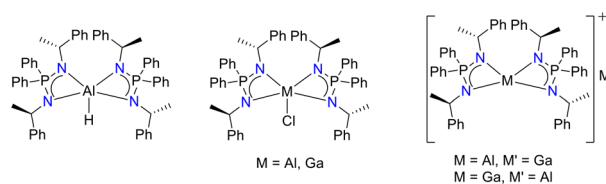

Fig. 7 Monometallic aluminum and gallium complexes of the $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}]_2$ ligand.¹³¹

$R' = (R)CH(CH_3)naph$) were synthesized by a salt metathesis reaction between $CuCl$ and lithium and the potassium salt of the iminophosphonamides $[Ph_2P\{(NR)(NR')\}_2M_2]$ ($M = Li$, for $R = R' = (R)CH(CH_3)Ph$ and $M = K$ for $R = R' = (R)CH(CH_3)naph$). Similar the one-pot reaction of $CuCl$, $K(NSiMe_3)_2$ and the iminophosphonamines $\{Ph_2P\{(NHR)(NR')\}$ ($R = (R)CH(CH_3)Ph$; $R' = 2,6\text{-}i\text{-}Pr_2C_6H_4$ and $R = R' = 2,6\text{-}i\text{-}Pr_2C_6H_4$) in equivalent ratios resulted in the formation of corresponding binuclear $Cu(I)$ complexes $[Ph_2P\{(NR)(NR')\}_2Cu_2]$ ($R = (R)CH(CH_3)Ph$; $R' = 2,6\text{-}i\text{-}Pr_2C_6H_4$ and $R = R' = 2,6\text{-}i\text{-}Pr_2C_6H_4$). Furthermore, when the deprotonation of the iminophosphonamine $\{Ph_2P(NHR)(NR')\}$ ($R = R' = (R)CH(CH_3)Ph$; and $R = (R)CH(CH_3)Ph$; $R' = 2,6\text{-}i\text{-}Pr_2C_6H_4$) was performed with ZnR_2 ($R = Me$ and Ph), it resulted in the formation of corresponding homoleptic complexes, $[Ph_2P\{(NR)(NR')\}_2Zn]$ ($R = R' = (R)CH(CH_3)Ph$ and $R = (R)CH(CH_3)Ph$; $R' = 2,6\text{-}i\text{-}Pr_2C_6H_4$). However, the deprotonation reaction between $Ph_2P\{(2,6\text{-}i\text{-}Pr_2C_6H_4N)_2\}H$ and $ZnPh_2$ resulted in the formation of a heteroleptic complex, $[Ph_2P\{(2,6\text{-}i\text{-}Pr_2C_6H_4N)_2\}ZnPh]$, due to the steric crowding from the Dipp (Dipp = $2,6\text{-}i\text{-}Pr_2C_6H_4$) group. The formation of all these complexes was proven by various analytical techniques such as single-crystal X-ray diffraction, multinuclear NMR spectroscopy, elemental analysis and IR spectroscopy. The solid-state PL measurement of these metal complexes in the temperature interval 5–295 K revealed that depending on the ligand substituents, the PL ranged from prompt fluorescence to TADF to long-lived phosphorescence. Additionally, step-scan FTIR spectroscopy was performed for $[\{Ph_2P(2,6\text{-}i\text{-}Pr_2C_6H_4N)_2\}Cu]_2$ to characterize the excited triplet state on the microscopic time scale.¹³²

 $\text{M} = \text{Zr}; \text{R} = \text{PE}; \text{R}' = \text{Dipp}$
 $\text{M} = \text{Hf}; \text{R} = \text{PE}; \text{R}' = \text{Dipp}$

Very recently, the group 4 (*i.e.*, Zr and Hf) metal complexes of chiral iminophosphonamide ligands $[\text{Ph}_2\text{P}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2]$ and $[\text{Ph}_2\text{P}\{\text{NDipp}\}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}]$ (Dipp = 2,6- $\text{Pr}_2\text{C}_6\text{H}_3$) have been reported.¹³⁴ These metal complexes were synthesized by adopting the amine elimination method between $[\text{M}(\text{NMe}_2)_4]$ (M = Zr and Hf) and $[\text{Ph}_2\text{P}\{\text{HN}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}_2]$ and $[\text{Ph}_2\text{P}\{\text{HNDipp}\}\{\text{N}(\text{R})\text{CH}(\text{CH}_3)\text{Ph}\}]$ in equimolar ratios (Scheme 63). The synthesized metal complexes were extensively characterized using several spectroscopic and analytical techniques. The structural determination of the complexes was carried out by using single-crystal X-ray diffraction.

Furthermore, the catalytic efficiency of the zirconium complex of the symmetric ligand $[\text{Ph}_2\text{P}\{(\text{NR})(\text{NR}')\}\text{Zr}(\text{NMe}_2)_3]$ ($\text{R} = \text{R}' = (\text{R})\text{CH}(\text{CH}_3)\text{Ph}$) and the hafnium complex of the unsymmetrical ligand $[\text{Ph}_2\text{P}\{(\text{NR})(\text{NR}')\}\text{Hf}(\text{NMe}_2)_3]$ ($\text{R} = (\text{R})\text{CH}(\text{CH}_3)\text{Ph}$ and $\text{R}' = \text{Dipp}$) was explored towards intramolecular hydroamination and hydroboration reactions, respectively.

4. Conclusions

In conclusion, we present an account of coordination compounds of nonchiral iminophosphoramides with s-block, p-block, transition, and f-block metals. The broad application of this ligand in wide areas of coordination chemistry is caused by various advantages: (i) The substituents on the nitrogen atoms can be varied by a wide range of functional groups including enantiomeric pure substituents. (ii) Due to the stepwise synthesis of iminophosphoramides, asymmetric substitution patterns can easily be realized. This allows for, *e.g.*, a convenient access to bridged bis(iminophosphoramides), which may act as chelating ligands. (iii) The steric demand of the iminophosphoramide can be adjusted due to

the flexible variation of the substituents on the nitrogen atoms. (iv) By having a phosphorous atom in the backbone of the ligand, the reaction can be monitored *in situ* by ^{31}P NMR spectroscopy. This makes iminophosphonamide superior to other N,N' -chelating ligands such as amidinates.

The review demonstrate that the iminophosphonamides differ more significantly from the amidinates than their formal similarity would suggest. However, the chemistry of iminophosphonamides in comparison to amidinates is still significant less developed. With this review, we hope to inspire chemists considering iminophosphonamides as suitable ligands for their research.

Author contributions

Both the authors did the literature research and wrote parts of the manuscript. PWR originated the idea and supervised the work.

Data availability

No primary research results, software or code have been included and no new data were generated or analysed as part of this review.

Conflicts of interest

There are no conflicts to declare.
