# Effects of PEDOT:PSS:GO composite hole transport layer on the luminescence of perovskite light-emitting diodes

Yuanming Zhou,<sup>ID</sup>\*<sup>ab</sup> Sijiong Mei,<sup>a</sup> Junjie Feng,<sup>a</sup> Dongwei Sun,<sup>a</sup> Fei Mei,<sup>\*ab</sup> Jinxia Xu<sup>ab</sup> and Xianan Cao<sup>c</sup>

Perovskite light-emitting diodes (PeLEDs) employing  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  as the emission layer (EML) and graphene oxide (GO) doped PEDOT:PSS as the hole transport layer (HTL) were prepared and characterized. GO doped in PEDOT:PSS can lead to the increased work function of HTL and lower the hole injection barrier at the HTL/ $\text{CH}_3\text{NH}_3\text{PbBr}_3$  interface, which facilitates the hole injection. Meanwhile, the optimized GO amount in PEDOT:PSS can help to reduce the quenching of luminescence occurring at the interface between HTL and perovskite. The luminance and current efficiency reach the maximum values of  $3302 \text{ cd m}^{-2}$  and  $1.92 \text{ cd A}^{-1}$  in PeLED with an optimized GO ratio (0.3), which increase by 43.3% and 73.0% in comparison with the undoped device, respectively. The enhanced luminescence of PeLEDs was caused by the combined effects of enhanced hole injection efficiency and the suppressed exciton quenching occurring at the HTL/EML interface. These results indicate that the introduction of traditional two-dimensional materials is a reasonable method for designing the structure of PeLEDs.

## 1. Introduction

Perovskite light-emitting diodes (PeLEDs) have been widely studied because of several advantages such as low-temperature solution processing, high photoluminescence quantum efficiency, high color purity and excellent carrier mobility.<sup>1–5</sup> A hole transport layer (HTL) is essential for the injection and transport of holes, which affects the number of holes in the region of the emission layer (EML), and correspondingly the radiative exciton recombination.<sup>6–9</sup> Poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) is a widely utilized HTL in PeLEDs, because the surface roughness of ITO and the injection barrier for holes can be reduced after inserting PEDOT:PSS between ITO and perovskite EML. However, because PEDOT:PSS is metallic and the excitons in perovskite materials possess long diffusion length, the quenching of excitons often happens at the interface between PEDOT:PSS and perovskite EML through non-radiative energy transfer and/or exciton dissociation pushed by the big discrepancy of energy levels between PEDOT:PSS and perovskite.<sup>3,10,11</sup> The energy level difference also impede the holes injecting from PEDOT:PSS to perovskite EML. Thus, PEDOT:PSS should be modified for improving the performance of PeLEDs.

Doping strategy is frequently selected to modify PEDOT:PSS in PeLEDs.<sup>2,12–14</sup> Several materials such as PFT<sup>2</sup> and  $\text{MoO}_3$  (ref. 12–14) have been doped in PEDOT:PSS to solve these problems and finally obtain the enhanced performance. Besides, two-dimensional (2D) materials may also be promising dopants due to their unique optoelectronic properties.

2D materials are composed of few-layer atoms or unit cells, such as graphene and its derivatives, transition metal dichalcogenides.<sup>15</sup> Among these materials, graphene oxide, which is a few-layer graphite oxide obtained by treating graphite with strong oxidizers. As reported in earlier literatures, the GO modified PEDOT:PSS has been used as anode and HTLs for enhancing the performance of optoelectronic devices such as light-emitting diodes (LEDs).<sup>15–22</sup>

GO doped PEDOT:PSS has been introduced as HTL for the purpose of improving the luminous characteristics of organic light-emitting diodes (OLEDs). Da Silva demonstrated phosphorescent OLEDs using the composite HTL, which show enhanced performance due to decreased hole injection barrier between ITO and PEDOT:PSS.<sup>16</sup> Dehsari reported the enhanced performance in polymer LEDs (PLEDs) with ultralarge GO sheet/PEDOT:PSS composite HTL.<sup>18</sup> Yang prepared  $\text{Alq}_3$ -based OLEDs using GO doped PEDOT:PSS HTL, and enhanced performance was caused by the increased hole injection efficiency, transparency and conductivity compared with the undoped device.<sup>20</sup> Diker prepared blue OLEDs using PEDOT:PSS:GO as HTL and obtain better performance.<sup>21</sup> These results manifest that the luminescence of OLEDs can be improved by doping GO in PEDOT:PSS from several aspects such as the enhanced injection

and transport of holes, reduced exciton quenching and improved surface morphology of ITO. Referred to these results in OLEDs, GO doped PEDOT:PSS is very likely to be a promising composite HTL in PeLEDs sharing the similar device structure, which may effectively enhance the performance of devices. However, there is no report about their application in PeLEDs. Besides, there is still large room for determining the fabrication technology and the corresponding physical mechanism of PeLEDs with GO doped HTLs.

In this work, GO modified PEDOT:PSS was utilized as HTL for enhancing the luminous characteristics of PeLEDs and the effects of GO were discussed. After doping GO in PEDOT:PSS, the PeLED has the maximum luminance of  $3302 \text{ cd m}^{-2}$  and the maximum current efficiency of  $1.92 \text{ cd A}^{-1}$ , which increase by 43.3% and 73.0% in comparison with the undoped device, respectively. The inherent physical mechanism was also discussed.

## 2. Experimental details

The PeLEDs were fabricated on cleaned ITO substrates, which were pre-treated by oxygen plasma to modify its work function and surface before the device fabrication. PEDOT:PSS (Clevios P AI4083) and graphene oxide (GO) aqueous dispersion ( $2 \text{ mg mL}^{-1}$ , Nanjing XFNANO) with desired volume ratios (1 : 0.1, 1 : 0.3, 1 : 0.5) were blended to obtain PEDOT:PSS:GO mixed solution. Methylammonium bromine ( $\text{CH}_3\text{NH}_3\text{Br}$ , Xi'an Polymer Light Technology) and Lead Bromide ( $\text{PbBr}_2$ , 99.999%, Sigma-Aldrich) with 2 : 1 molar ratio were dispersed in *N,N*-dimethylformamide (DMF, 99.9%, Sigma-Aldrich) solvent to obtain the perovskite precursor solution (5 wt%). In a nitrogen filled glovebox,  $\sim 40 \text{ nm}$  HTL was obtained by spin coating the pristine PEDOT:PSS or PEDOT:PSS:GO blended solution on ITO substrate at 8000 rpm for 30 s, followed by heating at  $120^\circ\text{C}$  for 15 min. Then,  $\sim 55 \text{ nm}$  perovskite EML was obtained by three-step spin coating technology, which can be found in our earlier literature.<sup>12</sup> Finally, a 30 nm electron transport layer (TPBi), a 0.5 nm electron injection layer (LiF) covered by a 100 nm Al cathode were deposited orderly in a thermal evaporation system. The effective emission area of each device is  $0.1 \text{ cm}^2$ .

A stylus profiler (Alpha-Step D-600) was used to determine the thickness of pure PEDOT:PSS film, GO modified PEDOT:PSS

films and perovskite films. A ultraviolet/visible spectrophotometer (HITACHI U-3900) and a luminescence spectrometer (HITACHI F-4600) were utilized to measure the transmittance and photoluminescence (PL) spectra, respectively. The ultraviolet photoelectron spectra (UPS) of HTLs were tested with an ESCALAB 250XI photoelectron spectroscopy using He I irradiation with  $h\nu = 21.2 \text{ eV}$  (Thermo Fisher). A scanning electron microscopy (FEI Sirion FEG) and a X-ray diffractometer (Panalytical Empyrean) was used to measure the surface morphology and XRD patterns of perovskite films. A source meter (Keithley 2400) and a multimeter (Keithley 2000) connected with a silicon photodetector were used to detect the optoelectronic characteristics of PeLEDs. A fiber-optic spectrometer (Ocean Optics USB4000-XR1) was used to observe the electroluminescence (EL) spectra of PeLEDs.

## 3. Results and discussion

The device structure of the PeLEDs using  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  as EML and GO modified PEDOT:PSS HTL is shown in Fig. 1a. The energy levels of individual layers in the PeLEDs were presented in Fig. 1b. The energy barrier for the holes injecting from pristine PEDOT:PSS to perovskite is large, which may lead to low hole injection efficiency. Doping GO in PEDOT:PSS is a possible way for adjusting the work function of the HTL and subsequently the injection ability of holes.

Fig. 2 shows the ultraviolet photoelectron spectra (UPS) of HTLs. The work function (WF) can be extracted by subtracting secondary electron cutoffs from the excitation energy ( $21.2 \text{ eV}$ ).<sup>23–25</sup> The secondary electron cutoff of pristine PEDOT:PSS film, PEDOT:PSS:GO film with the GO ratio of 0.1, 0.3 and 0.5 was obtained to be 16.37, 16.28, 16.23, and 16.18 eV, respectively. Thus, the WF of the pure PEDOT:PSS film was calculated to be 4.83 eV, which is well consistent with the previously reported values.<sup>23–25</sup> On increasing the GO ratio from 0.1 to 0.5, the WF of the GO-doped film increases from 4.92 eV to 5.02 eV. Therefore, the increased work function of the GO-doped composite film reduces the energy barrier for hole injection between the composite HTL and  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  EML, which can help to elevate the hole injection efficiency.

Fig. 3 shows XRD patterns of  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  films spin coated on the PEDOT:PSS films doped with different GO amount. Two

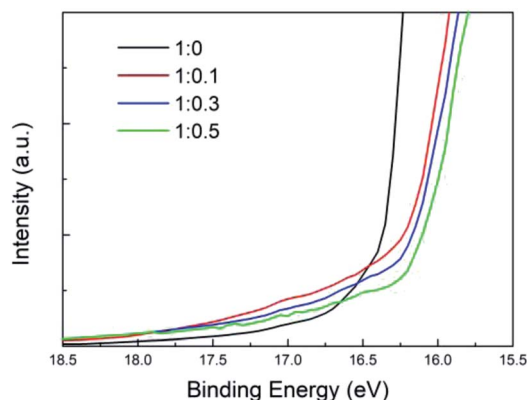

Fig. 2 Ultraviolet photoelectron spectra (UPS) of PEDOT:PSS:GO composite films prepared on ITO substrate.

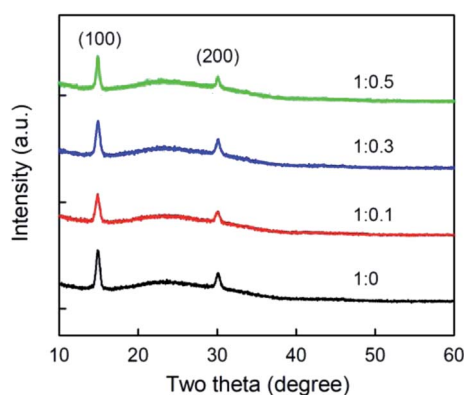

Fig. 3 XRD patterns of the  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  films on the PEDOT:PSS films doped with different GO amount.

typical peaks were found at  $15^\circ$  and  $30^\circ$ , which can be attributed to (100) and (200) crystal planes, respectively.<sup>12</sup> In comparison with the reference sample prepared on pure PEDOT:PSS, slightly lower intensities of diffraction peaks were observed for those on all the GO-doped composite films. The diffraction peak intensities of four samples are comparable, suggesting that the GO doping does not affect the structure and crystallinity of perovskite films significantly.

Fig. 4 presents the SEM images of  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  films spin coated on the PEDOT:PSS films doped with different GO amount. As shown, the surface morphology of the perovskite film is affected by the GO amount in composite HTL. When using the pure PEDOT:PSS, the rough surface of perovskite film is covered by several large flakes. On increasing the GO ratio from 0 to 0.3, the large flakes disappear gradually and small grains form simultaneously. Meanwhile, for the  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  film coated on the PEDOT:PSS:GO (1 : 0.3) HTL, uniform and compact perovskite films can be obtained. However, when the GO ratio was further increased to 0.5, the perovskite film with poor coverage was found, which may be attributed to the excessive amount of GO. These results indicated that the appropriate amount of GO content can help to obtain the better surface morphology of perovskite films.

Fig. 5a presents the steady-state PL spectra of  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  films tested with a 315 nm excitation wavelength. A typical peak at  $\sim 528$  nm was found in all the PL spectra. On increasing the GO ratio from 0 to 0.3, the PL peak intensity increases, while the further increased GO leads to the decreased PL intensity. It is indicated that the optimized GO amount is essential for suppressing the quenching of excitons occurred at the interface between HTL and  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  EML, while the overweight GO

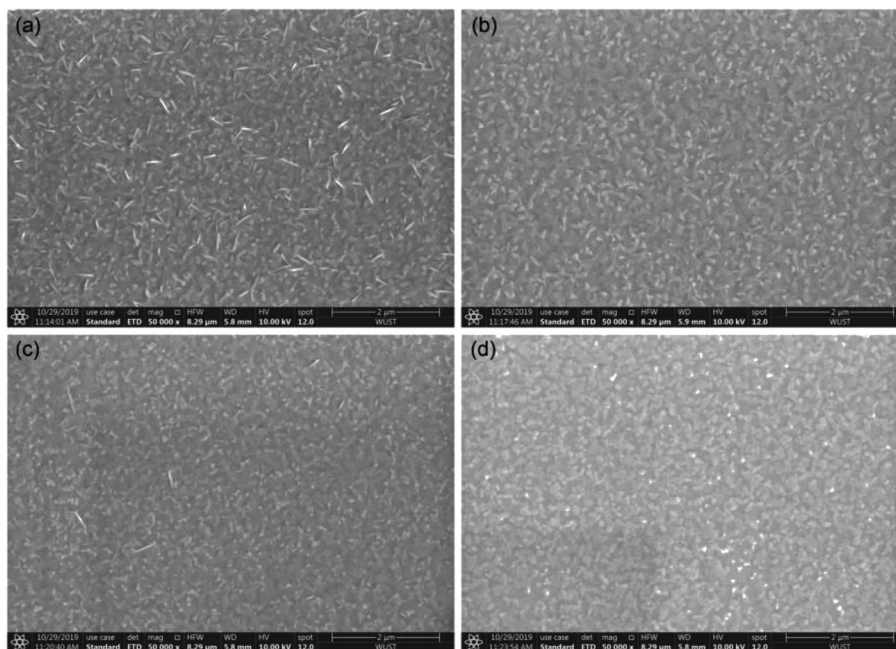

Fig. 4 SEM images of the  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  films on the GO-doped composite films with different GO concentration of (a) 1 : 0, (b) 1 : 0.1, (c) 1 : 0.3, (d) 1 : 0.5.

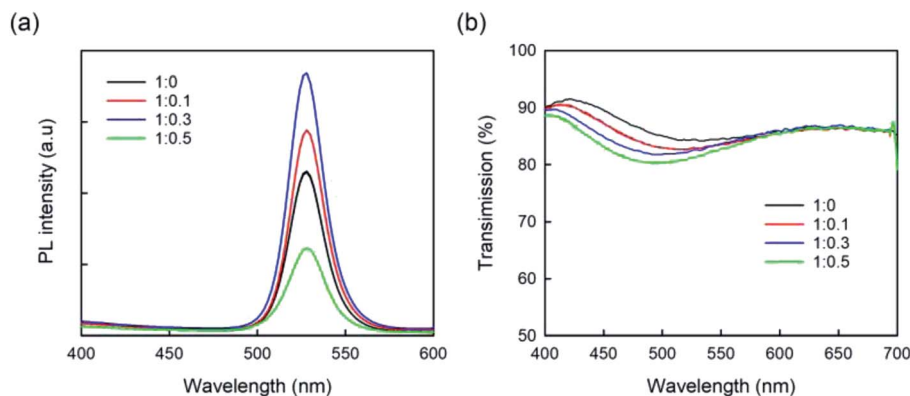

Fig. 5 (a) PL and (b) transmittance spectra of the  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  films covered on the PEDOT:PSS films doped with different GO amount.

is not beneficial. On one hand, the increased amount of GO could reduce the contact among PEDOT:PSS and excitons in the EML to some extent, which facilitates the blocking of exciton quenching. Meanwhile, the increased work function of composite HTL reduces the hole injection barrier and prevents the exciton dissociation caused by the large discrepancy of energy levels between PEDOT:PSS and  $\text{CH}_3\text{NH}_3\text{PbBr}_3$ , leading to the decreased quenching of excitons at the HTL/EML interface.<sup>3,11</sup> Similar results have been reported in polymer LEDs with PEDOT:GO composite HTLs, in which GO reduces the quenching of excitons at HTL/Super Yellow (SY) interface.<sup>26</sup> Besides, exciton quenching at the GO/SY interface is found to be

much less than that at the PEDOT:PSS/SY interface.<sup>27</sup> On the other hand, the excessive GO may induce defect states at the HTL/perovskite EML interface, which leads to the decreased PL intensity. It is found that the trend of the PL peak intensity is in accordance with that of the SEM images. In detail, as the GO ratio increases from 0 to 0.3, the dense and smooth perovskite film indicates the formation of high-quality film, and correspondingly the increased PL strength was obtained. However, when the GO ratio was further increased to 0.5, the decreased PL strength corresponds to the poor-coverage perovskite film.

Fig. 5b shows the wavelength-dependent transmittance of  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  films on the PEDOT:PSS films doped with

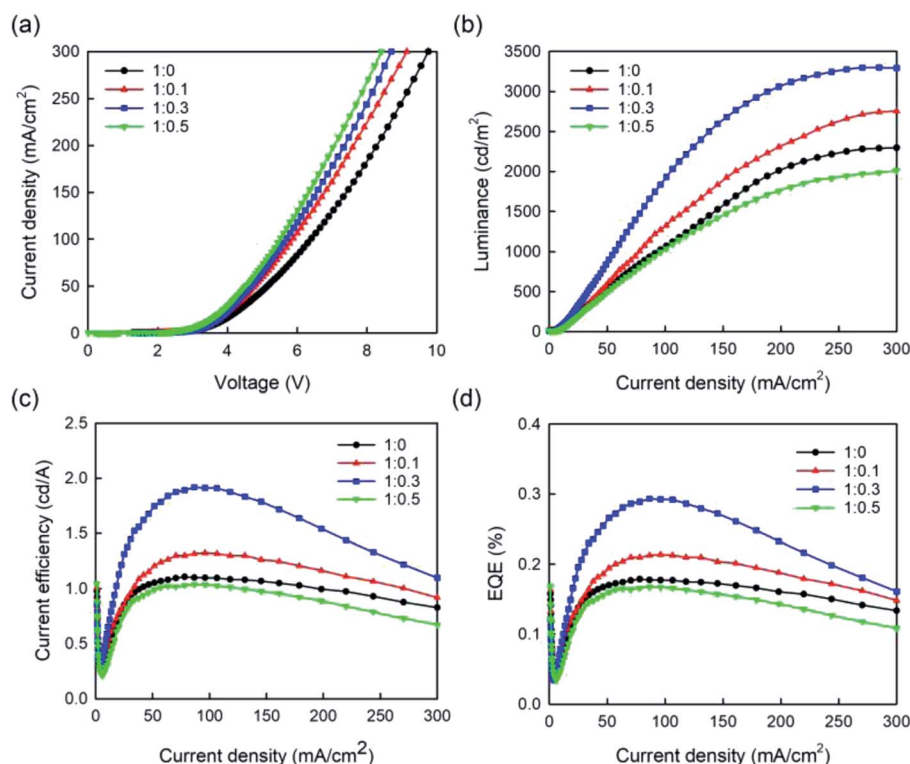

Fig. 6 (a) Current density vs. voltage, (b) luminance vs. current density, (c) current efficiency vs. current density, (d) external quantum efficiency vs. current density curves of PeLEDs with PEDOT:PSS HTLs doped with different GO content.

Table 1 The device parameters of our PeLEDs

PEDOT:PSS:GO	Max. luminance ( $\text{cd m}^{-2}$ )	Max. CE ( $\text{cd A}^{-1}$ )	Max. EQE (%)	Turn-on voltage (V)
1 : 0	2305	1.11	0.17	4.30
1 : 0.1	2771	1.34	0.21	4.07
1 : 0.3	3302	1.92	0.29	3.94
1 : 0.5	2013	1.04	0.16	3.87

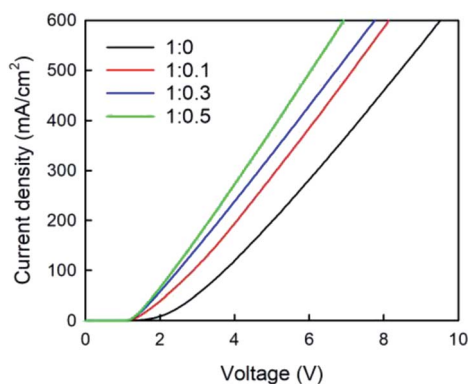

Fig. 7 The voltage dependence of current density for the hole-only devices utilizing PEDOT:PSS HTLs doped with different GO amount.

different GO amount. On increasing the GO ratio from 0 to 0.5, the transmittance near 528 nm decreases slowly. It is noted that the transmittance of the composite film with the largest GO concentration (1 : 0.5) is still beyond 80% near 528 nm. The comparable values of transmittance were found for four samples, suggesting that the GO doping does not block the light emitting through the HTL region significantly.

Fig. 6a shows the voltage dependence of current density for the PeLEDs with PEDOT:PSS HTLs doped with different GO content, respectively. The turn-on voltage, which is determined with the operating voltage at  $\sim 1 \text{ mA cm}^{-2}$ , was lowered from 4.30 V to 3.87 V monotonically with the increased GO ratio from 0 to 0.5. In addition, the current density increases with the increase of the GO

amount, suggesting more efficient hole injection. Fig. 6b–d show the luminance, current efficiency (CE), and external quantum efficiency (EQE) of our PeLEDs as functions of current density. The obtained parameters of our PeLEDs are listed in Table 1. For the undoped control PeLED using pure PEDOT:PSS HTL, the maximum values of luminance, CE and EQE are  $2305 \text{ cd m}^{-2}$ ,  $1.11 \text{ cd A}^{-1}$  and 0.17%, respectively. On increasing the GO ratio to the optimized GO ratio of 0.3, the luminance and CE reach  $3302 \text{ cd m}^{-2}$  and  $1.92 \text{ cd A}^{-1}$ , which increase by 43.3% and 73.0% in comparison with the values of the undoped device, respectively. However, the further increase of GO ratio to 0.5 leads to the decreased efficiency for our device.

In order to determine the role of GO on the hole injection, hole-only devices have also been prepared and tested. Fig. 7 presents the current density of the hole-only devices as a function of voltage, which possess the structure of ITO/HTL/ $\text{CH}_3\text{NH}_3\text{PbBr}_3$ /NPB/Al. As shown, after the GO doping in PEDOT:PSS, the current density of the doped sample increases monotonically in comparison with that without GO doping, indicating the enhanced injection ability for holes. It can be caused by the increased WF of HTL and the lower hole injection barrier between composite HTLs and  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  after the GO doping.<sup>19</sup> Besides, exciton quenching at the HTL/perovskite interface is another important factor. In LEDs, the external quantum efficiency (EQE) of devices is defined by the ratio between the number of output photons from the device and the number of charges injected to the device. On increasing the GO ratio from 0 to 0.3, the improved efficiency (CE and EQE) of PeLEDs in Fig. 6 can be caused by the combined effects of the enhanced hole injection and reduced exciton quenching evidenced by the PL spectra. The further increase of GO leads to the further enhancement of hole injection shown in Fig. 7. However, the efficiency of PeLED decreases with the excessive GO, which can be mainly explained by the increased exciton quenching shown in PL spectra. Therefore, the increased efficiency of PeLEDs using an optimized PEDOT:PSS:GO as HTL can be caused by the better injection of holes and the suppressed quenching of excitons at the interface between  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  and HTL doped with GO.

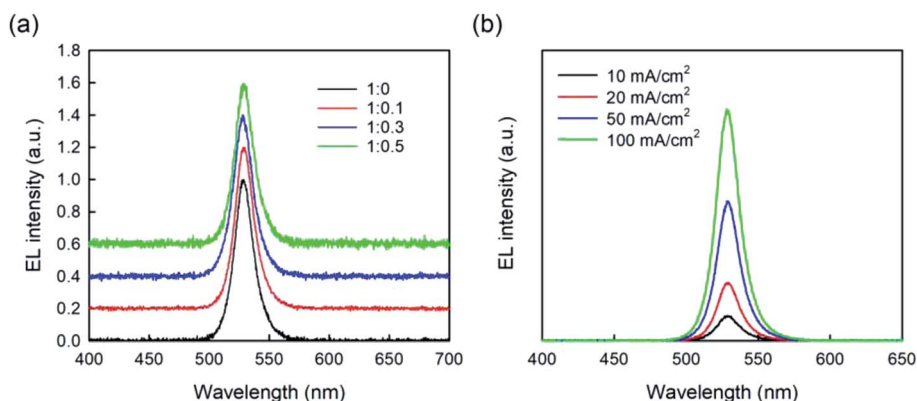

Fig. 8 (a) Normalized EL spectra of the PeLEDs with PEDOT:PSS HTLs doped with different GO amount tested at the current density of  $50 \text{ mA cm}^{-2}$ . (b) EL spectra for the PeLED with the optimal PEDOT:PSS:GO (1 : 0.3) HTL tested by using different current densities.

Fig. 8a shows the normalized EL spectra of our PeLEDs, suggesting that all the EL spectra with a peak at  $\sim 528$  nm are nearly the same. It is suggested that the GO doping does not change the emission profiles of our devices. Meanwhile, the EL spectra for the PeLED with the optimal PEDOT:PSS:GO (1 : 0.3) HTL were measured by using different current densities and presented in Fig. 8b. On increasing the current density, the EL peak intensity of the device increases gradually. Meanwhile, the same peak position at  $\sim 528$  nm was found in the PeLED at different current densities have, indicating the color stability of PeLEDs.

## 4. Conclusions

In conclusion, we reported the enhanced efficiency of PeLEDs by employing GO modified PEDOT:PSS HTLs. On increasing the GO ratio from 0 to 0.5, the increased work function from 4.83 eV to 5.02 eV was found in the composite films, suggesting the increased work function of the composite HTL, which reduces the energy level difference between HTL and perovskite for enhanced hole injection. Meanwhile, the optimized GO amount in PEDOT:PSS can help to reduce the quenching of luminescence occurred at the interface between HTL and  $\text{CH}_3\text{NH}_3\text{PbBr}_3$ . On increasing the GO ratio from 0 to 0.3, the maximum value of luminance increases from  $2305 \text{ cd m}^{-2}$  to  $3302 \text{ cd m}^{-2}$ , while the maximum CE increases from  $1.11 \text{ cd A}^{-1}$  to  $1.92 \text{ cd A}^{-1}$ . Further increase of the GO ratio to 0.5 leads to the decrease of luminance and CE. In comparison with the undoped device, the maximum luminance and CE increase by 43.3% and 73.0% in PeLED with an optimized GO ratio (0.3) respectively. The enhanced performance of our PeLEDs can be induced by the better hole injection efficiency and suppressed quenching of excitons at the interface between HTL and  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  EML. These results provide an important approach for designing high-efficiency PeLEDs with 2D materials.
