Injectable hydrogels for the delivery of nanomaterials for cancer combinatorial photothermal therapy

Rita Lima-Sousa,[a] Cátia G. Alves,[a] Bruna L. Melo,[a] Francisco J. P. Costa,[a] Micaela Nave,[a] André F. Moreira,[a] António G. Mendonça,[a,b] Ilídio J. Correia *[a] and Duarte de Melo-Diogo*[a]

Progress in the nanotechnology field has led to the development of a new class of materials capable of producing a temperature increase triggered by near infrared light. These photothermal nanostructures have been extensively explored in the ablation of cancer cells. Nevertheless, the available data in the literature have exposed that systemically administered nanomaterials have a poor tumor-homing capacity, hindering their full therapeutic potential. This paradigm shift has propelled the development of new injectable hydrogels for the local delivery of nanomaterials aimed at cancer photothermal therapy. These hydrogels can be assembled at the tumor site after injection (*in situ* forming) or can undergo a gel–sol–gel transition during injection (shear-thinning/self-healing). Besides incorporating photothermal nanostructures, these injectable hydrogels can also incorporate or be combined with other agents, paving the way for an improved therapeutic outcome. This review analyses the application of injectable hydrogels for the local delivery of nanomaterials aimed at cancer photothermal therapy as well as their combination with photodynamic-, chemo-, immuno- and radio-therapies.

1. Introduction

Cancer is one of the leading causes of death worldwide, hence engaging much effort from the scientific community and industry.[1,2] To date, the intravenous administration of chemotherapeutic drugs (chemotherapy) has been the most widely applied therapeutic strategy for this disease.[3] However,

Rita Lima-Sousa

Rita Lima-Sousa received her B.Sc. in Biochemistry and M.Sc. in Biomedical Sciences from the Universidade da Beira Interior in 2016 and 2018, respectively. Currently, Rita Lima-Sousa is a Ph.D. student in Biochemistry at the same university (with a Ph. D. scholarship awarded by FCT) and is developing her thesis in Prof. Ilídio J. Correia's group. Her research interests are focused on the development and functionalization of graphene family nanomaterials and injectable hydrogels for application in cancer photothermal therapy and biomedicine.

Ilídio J. Correia

Ilídio J. Correia is a Full Professor in the department of Health Sciences at the Universidade da Beira Interior. He obtained his B.Sc. and Ph.D. degrees in Biochemistry from the University of Lisbon in 1998 and the New University of Lisbon in 2003, respectively. His research group is involved in the development of skin and bone substitutes, drug delivery systems, as well as in vitro *3D cell culture models of cancer.*

this route has some severe side effects associated with its non-specificity towards cancer cells, ultimately leading to systemic toxicity.[3] To overcome such constraints, the cancer research community has been focused on developing new therapeutic weapons.[4–7]

A more up-to-date anticancer strategy that is currently under investigation relies on the use of nanomaterials-mediated photothermal therapy (PTT).[8–11] In this approach, nanostructures with photoresponsiveness are administered intravenously, accumulate at the tumor site and, upon irradiation with near infrared (NIR, 750–1000 nm) light, produce a local temperature increase, resulting in the death of cancer cells.[12–14] Considering that NIR radiation minimally interacts with biological components (*e.g.*, water, melanin), its use is crucial for achieving a high penetration depth and negligible off-target heating.[12] Hence, PTT mediated by nanomaterials may allow accurate spatio-temporally controlled treatment.[15] Inorganic nanostructures such as anisotropic gold nanoparticles (*e.g.*, gold nanorods,[16] gold nanostars[17]), carbon-based nanomaterials (*e.g.*, carbon nanotubes,[18] graphene oxide (GO),[19] reduced graphene oxide (rGO)[20]), or transition metal dichalcogenides (*e.g.*, MoS_2 [21] and WS_2 nanosheets[22]) have been employed for cancer PTT due to their high NIR absorption and photothermal capacity. In turn, NIR-absorbing small molecules (*e.g.*, indocyanine green (ICG),[23] IR780,[24] IR820[25]) have been loaded into nanostructures due to their multimodal character and biodegradability, being promising nanoagents for cancer PTT. Such small molecule-based photothermal agents may also be covalently modified (*e.g.*, with polymers, amino acids) to generate self-assembling nanostructures intended for cancer PTT.[26,27]

Notwithstanding the nanoparticles' anticancer potential, their translation to the clinic has been slow. Nanomaterials administered systemically (*i.e.*, by intravenous injection) rely heavily on the differently sized fenestrae of tumor vasculature to passively accumulate at the tumor zone (enhanced permeability and retention (EPR) effect).[28,29] However, only a very small portion of the intravenously administered nanoparticles reaches the tumor site (less than 1% (median)).[30] Besides this, the models currently available for the pre-clinical screening of nanomaterials also show an exaggerated EPR effect.[31] In fact, the EPR effect is not ubiquitously present on human solid tumors, which further hinders nanomaterials' translation.[31,32]

In order to benefit from the potential of nanomaterials-mediated PTT, it is crucial to overcome their systemic administration-related issues. In this regard, the incorporation of nanomaterials into macroscale systems (*e.g.*, microneedles, injectable hydrogels, scaffolds) has been receiving great attention.[33–35] These macroscale systems can be locally injected/implanted into the tumor zone, thus sustaining the delivery of the nanoparticles into the diseased site.[36] Moreover, this approach can maximize the accumulation of nanoparticles in the tumor as well as reduce their leakage to adjacent tissues, avoiding possible side effects.[36] Among the different types of macroscale systems, injectable hydrogels have received great interest due to their unique set of properties.[37,38]

These injectable hydrogels have a straightforward formulation and can be assembled at the tumor site (*in situ*-forming hydrogels) or can undergo a gel–sol–gel transition during injection (shear-thinning/self-healing hydrogels).[37,39,40] In this way, these can be administered through a minimally invasive procedure and can reach deeper tumors when compared with microneedle patches.[41,42] Besides coordinating the delivery of the NIR light-responsive nanoparticles directly into the tumor site, the hydrophilic network of the hydrogels can also incorporate other agents (*e.g.*, drugs, immunostimulants), opening a venue for combinatorial PTT approaches.[43,44] For instance, Huang *et al.* compared the biodistribution of doxorubicin (DOX) and DOX-loaded nanoparticles (both administered by intravenous injection) with that attained using an injectable hydrogel containing DOX-loaded nanoparticles (by peritumoral injection).[45] The free DOX and DOX-loaded nanoparticles achieved tumor uptake, but their concentration at this site decreased after 1 day. In turn, the injectable hydrogel containing the DOX-loaded nanoparticles promoted a higher tumor accumulation of this agent (at least for 21 days) with minimal distribution to off-target organs (*e.g.*, liver, spleen, lungs). In fact, several studies have demonstrated that the delivery of nanostructures (or drugs) using injectable hydrogels results in a prolonged tumor uptake and/or minimal off-target accumulation.[46,47] Depending on the components used for their production, the injectable hydrogels also display good physical and chemical properties, biodegradability, and biocompatibility.[34]

In this review, the application of injectable hydrogels for the local delivery of nanoparticles aimed at cancer PTT as well as their potential for combinatorial PTT is analyzed. Firstly, an overview of the properties and capabilities of injectable hydrogels designed for tumor-confined delivery of nanomaterials will be provided (section 2). Afterwards, the application of injectable hydrogels for guiding nanomaterials-mediated PTT

Duarte de Melo-Diogo

Duarte de Melo-Diogo received his B.Sc. and M.Sc. degrees in Biomedical Sciences from the Universidade da Beira Interior (UBI) in 2012 and 2014, respectively. In 2018, Duarte de Melo-Diogo received his Ph.D. degree in Biochemistry from the same university. Currently, he is an Invited Assistant Professor at UBI and Junior Researcher at the Centro de Investigação em Ciências da Saúde (CICS-UBI). His research interests are focused on the biomedical application of graphene family nanomaterials, production of functional nanostructures for cancer therapy and development of macroscale delivery systems.

will be analyzed (section 3). Then, the use of injectable hydrogels for nanomaterials-mediated PTT in synergy with other therapeutic modalities (photodynamic-, chemo-, immuno- and radio-therapies) will be discussed (section 4). Finally, an outlook regarding the state-of-the-art and future directions is provided (section 5). For the sake of brevity, this review will be focused on hydrogels for cancer combinatorial-PTT that are locally administered by intratumoral/peritumoral injections.

2. Overview of injectable hydrogels for the delivery of nanomaterials for cancer PTT

Injectable hydrogels allow local nanoparticle delivery in a relatively non-invasive manner (*i.e.*, through injection) when compared with their implantable equivalents.[48–50] This can greatly reduce discomfort and risk of infection.[49,50]

In general, two main types of injectable hydrogels have been used for the delivery of nanoparticles aimed at cancer PTT: injectable *in situ*-forming hydrogels and shear-thinning/self-healing hydrogels.[37,39,40] Regarding the former, as their name states, these are formed *in situ* (*i.e.*, at the tumor site). In brief, the procedure for injectable *in situ*-forming hydrogel administration is based on the loading of precursor solutions (polymeric solutions and/or crosslinking agents) and NIR-responsive nanoparticles into a syringe.[43,44,48,51] This mixture is then administered at the tumor site, allowing the hydrogel formation *in situ* by a crosslinking reaction, the nanoparticles being entrapped within the polymeric structure.[6] Thus, the hydrogel should have a fast gelation time to prevent premature leakage of the therapeutic nano-agents.[52] At the same time, the hydrogel must also allow the sustained release of the entrapped molecules.[53] Then, the tumor area is irradiated with a NIR light, and an on-demand temperature increase occurs after the nanomaterials' interaction with this radiation.

In the case of shear-thinning/self-healing hydrogels, these are pre-formed in the syringe.[54] Upon injection at the tumor site, the generated shear force allows the dissociation of the crosslinking bonds, and the hydrogel extravasates through the needle due to a decrease in its viscosity.[54,55] When this force is no longer applied, the crosslinking interactions are rebuilt (self-healing) and the hydrogel network is restored at the tumor site.[54,55] Afterwards, the nanomaterials' PTT can be initiated with the irradiation of the tumor zone with NIR light. This type of hydrogel allows for a more homogeneous encapsulation of the nanomaterials, injection without clogging and controlled release of the payload.[55]

2.1. Crosslinking mechanisms

Injectable hydrogels can be classified according to their crosslinking mechanism.[48,53] Chemically crosslinked hydrogels are formed by covalent bonds between the polymeric components and are characterized by higher mechanical strength and physical stability, giving them a prolonged degradation time.[6] It should be noted that some chemical reactions may require the assistance of additional agents such as photoinitiators, catalyzers, or organic solvents, demanding special attention to ensure the hydrogel's biocompatibility.[6,56] The typical reactions in chemically crosslinked injectable hydrogels are (i) Schiff base reactions between an amine and carbonyl-containing aldehyde/ketone; (ii) Michael addition reactions where there is a nucleophilic addition to an unsaturated carbonyl compound, like α,β-unsaturated carbonyl; (iii) disulfide bond formation between peripheral thiol groups; (iv) Diels–Alder "click" reaction between a conjugated diene and an alkene/alkyne; (v) polymerization in the presence of a photoinitiator; and (vi) azide–alkyne cycloaddition between these two functional groups, with Cu(I) as a catalyst (Fig. 1).[6,48,57–63]

Physically crosslinked hydrogels are formed by non-covalent interactions, displaying excellent injectability and biocompatibility.[6] However, these types of hydrogels tend to have a relatively low mechanical strength.[40,48] The typical reactions in physically crosslinked hydrogels are (i) hydrophobic interactions between hydrophobic segments that result in aggregation in aqueous solutions; (ii) hydrogen bonding between hydrogen atoms in highly electronegative groups and other electronegative atoms; (iii) ionic crosslinking formed by electrostatic forces between two oppositely charged molecules; (iv) host–guest interactions between a host molecule that includes/complexes a guest molecule in their structure; and (v) π–π interactions between the aromatic ring of two molecules rich and short of electrons (Fig. 1).[6,48,51,64–69]

2.2. Stimuli-responsiveness

Injectable hydrogels can also be engineered to be sensitive to external or internal (*i.e.*, endogenous) stimuli.[70–72] This responsiveness can be applied in triggering the hydrogels' assembly/disassembly at the tumor site, their degradation, and in the release of the incorporated nanomaterials.[71,73]

Regarding external stimuli, injectable hydrogels can, for example, be light-responsive (*e.g.*, UV or NIR light).[74–76] The application of light may (i) induce the photopolymerization or photooxidation of crosslinking bonds mediated by the initiator; (ii) cause photoisomerization; or (iii) generate a temperature increase (mediated by the loaded photothermal agents) that alters the hydrogel's solid form.[71,77,78] This photo-induced heat can also be used to induce a controlled release of nanotherapeutic agents.[51] For instance, Wang and co-workers prepared a light-responsive hydrogel using methacrylic anhydride-modified chitosan and poly(*N*-isopropylacrylamide) (PNIPAM) that incorporated carbon-based nanostructures and DOX.[79] The combination of irgacure 2959 (photoinitiator) and UV light triggered a photocrosslinking process between the methacrylic groups that led to the hydrogel's assembly. In turn, the photothermal effect induced by the carbon-based nanostructures after NIR irradiation induced the shrinking of the hydrogel (behavior attributed to PNIPAM) and triggered the DOX release.[79]

Moreover, by incorporating superparamagnetic nanostructures (*e.g.*, Fe_3O_4 nanoparticles) into the injectable hydro-

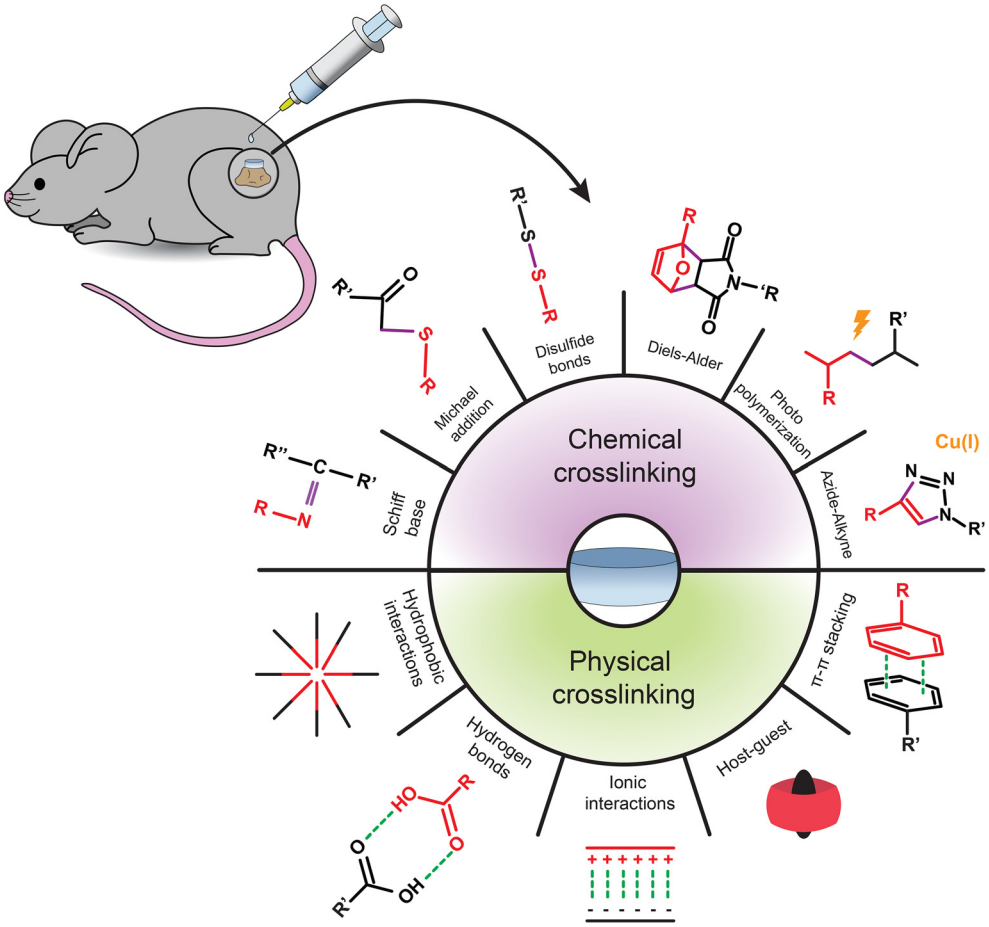

Fig. 1 Schematic illustration of the chemical and physical crosslinking methods used for the assembly of injectable hydrogels.

gels, it is possible to attain responsiveness to magnetic fields.[56,80] The interaction of these nanostructures with the magnetic field can also produce a local temperature increase that can change the hydrogel's properties (*e.g.*, increasing the drug release).[80]

Concerning internal/endogenous stimuli, injectable hydrogels can be engineered to be responsive to body temperature.[81,82] Moreover, the tumor microenvironment also displays a set of characteristics that can be used as internal/endogenous stimuli (lower pH or overexpression of specific enzymes (*e.g.*, matrix metalloproteinases (MMPs)).[70]

There can be two types of temperature-responsiveness: injectable hydrogels' viscosity can decrease or augment with the temperature increase.[44,72,83] The former can be helpful in terms of release of loaded therapeutic agents, whereas the latter is more advantageous for efficient gelation in the tumor area. One popular strategy explores the use of polymeric formulations that present a low viscosity at room temperature (to make injection easier) and then, after injection in the tumor zone, undergo a sol-to-gel transition at body temperature.[66,83,84] The best-known polymers with thermal responsiveness include the Pluronic family, cellulose, chitosan, or agarose derivatives.[84] For example, Zheng *et al.* developed a temperature-responsive hydrogel composed of chitosan and β-glycerophosphate incorporating DOX and poly(ethylene glycol) (PEG)-functionalized MoS_2/Bi_2S_3 nanosheets for cancer therapy.[85] Upon mixing, these components could be loaded into a syringe and easily extruded. This formulation gellified at 37 °C due to a combination of hydrogen bonding and electrostatic and hydrophobic interactions between chitosan and β-glycerophosphate.[85]

Regarding pH-responsive injectable hydrogels, one possible approach explores crosslinking bonds that are stable at physiological pH but suffer rapid breakdown in the acidic conditions found within the tumor extracellular fluid.[34,86] Qu and colleagues developed an injectable hydrogel based on the covalent and pH-sensitive Schiff base bond between *N*-carboxyethyl chitosan (CEC) and dibenzaldehyde-terminated PEG (PEG-DA) for the intratumoral delivery of DOX.[87] At the mildly acidic tumor pH, the primary amine groups of CEC become positively charged, weakening the Schiff base crosslinking. Such change promoted the hydrogel's degradation and accelerated the release of the loaded cargo.[87]

Enzyme-responsive hydrogels aim to take advantage of enzymes overexpressed at the tumor site.[53] For instance, the tumor microenvironment has high amounts of MMPs that

degrade the basement membrane and extracellular matrix, playing an important role in several cancer processes.[88] Generally, the preparation of enzyme-responsive hydrogels is based on the incorporation of enzyme-cleavable crosslinkers (*e.g.*, short peptides[89]) and enzyme-cleavable polysaccharides (*e.g.*, hyaluronic acid (HA) since it is degraded by hyaluronidase[90]). Li *et al.* developed an enzyme-responsive injectable hydrogel formulated through Michael addition reactions between acrylated-HA and cysteine-modified peptides containing an MMP-2-cleavable sequence (GPQGIWGQ), that also incorporated DOX-loaded micelles.[91] In the presence of MMP-2, this hydrogel promoted a 1.45-times greater DOX release than in the absence of MMP-2.

3. Injectable hydrogels for cancer PTT

Injectable hydrogels can incorporate NIR-responsive nanomaterials into their hydrophilic structure, protecting them from degradation and sustaining their tumor-confined delivery.[43] In this way, injectable hydrogels have been explored for the local delivery of nanomaterials aimed at cancer PTT (Table 1) (Fig. 2A–D).

When the radiation interacts with the photothermal nanoagent incorporated into the tumor-confined hydrogel, it is absorbed, and the energy is released as heat.[43] If the final temperature at the tumor site is around 41–45 °C there can be (i) changes in cells' metabolic functions, (ii) inhibition of the DNA repair mechanisms, (iii) increase in the blood flow at the tumor site, (iv) increase in the oxidative stress and formation of reactive oxygen species (ROS), (v) a rise in the infiltrated immune cells, and (vi) sensitization of cells to the action of other therapies.[8,92–95] However, these effects are sublethal and can be reversible. On the other hand, local temperature increases to about 50 °C (or above) induce permanent damage: (i) the cell membrane collapses, (ii) the proteins denature, and (iii) the enzymatic and mitochondrial functions are rendered dysfunctional.[13,94,96] Such effects are non-reversible and ultimately lead to cell death by necrosis.[97,98] The cellular and molecular mechanisms prompted by these photothermally induced events have been extensively reviewed elsewhere.[99–103]

Additionally, the temperature increase that occurs during irradiation can also affect the structure of thermosensitive hydrogels (discussed in section 2). CuS nanodots, polydopamine (PDA) nanostructures, gold-based nano-systems, GO derivatives, ICG and IR820 are some NIR-responsive agents that have been incorporated into injectable hydrogels intended for cancer PTT.[104–110]

He and co-workers developed an injectable hydrogel composed of silk fibroin that incorporated GO complexed with upconversion nanoparticles (UCNP).[111] This hydrogel was formed through hydrophobic interactions that changed the silk fibroin from a random coil structure to the more stable β-sheet conformation.[112] In this system, UCNP were used as imaging agents (upon excitation with 980 nm light) while GO acted as photothermal agent (upon exposure to 808 nm radiation).[111] After administration of the macroscale formulation into the breast tumor of mice and *in situ* gelation, this area was irradiated with 808 nm light (1 W cm^{-2}, 5 min), reaching a temperature increase to about 57 °C that resulted in potent tumor regression.[111]

In another work, Cao *et al.* developed a poly (D,L-lactic acid-*co*-glycolic acid)-*b*-PEG-*b*-poly(D,L-lactic acid-*co*-glycolic acid)-based injectable hydrogel incorporating ancient ink nanoparticles as the PTT agent for colon cancer therapy.[113] This injectable hydrogel displayed a thermo-responsive assembly, achieving gelation when the temperature increased from 25 °C to 37 °C (physiological temperature). When the administered injectable hydrogel was subjected to NIR light (1064 nm, 0.5 W cm^{-2}, 15 min), it could produce a temperature increase to approximately 48.7 °C, resulting in a tumor growth reduction of about 84%.[113]

4. Injectable hydrogels for cancer combinatorial therapy

Injectable hydrogels can also be used for the local co-delivery of photothermal nanostructures and other therapeutic agents.[37,56] This combinatorial approach opens a venue for exploring the strong aspects of each therapeutic regimen, possibly leading to synergistic effects (Table 2).[72,127] This can also lead to a reduction of the required NIR laser and nanoparticle doses. This type of combinatorial therapy mediated by the injectable hydrogels is also important to achieve a greater therapeutic outcome, especially when the standalone PTT is not capable of destroying the residual cancer cells.

4.1. Injectable hydrogels for cancer photodynamic-PTT

Injectable hydrogels that incorporate photothermal nanoagents and photosensitizers have triggered the interest of researchers (Table 2). Upon interaction with laser light, the photosensitizers are able to create ROS such as singlet oxygen, hydrogen peroxide, superoxide anion and hydroxyl radicals (photodynamic therapy (PDT)) (Fig. 2E–H).[128] At suitable levels, these ROS are extremely toxic to cancer cells since these can (i) affect the DNA and the permeabilization of the mitochondria's outer membrane, (ii) cause damage to the tumor vasculature, and (iii) induce an inflammatory response.[129–131] Interestingly, the ROS produced during PDT can also act as initiators in the photopolymerization/photocrosslinking of some injectable hydrogels.[132] To date, different photosensitizers (*e.g.*, IR780,[51] ICG,[133] Ce6[134]) have been incorporated into injectable hydrogels aimed at cancer therapy, either dispersed in the gels' hydrophilic network or encapsulated within the nanomaterials.

Besides the standalone effects of the nanomaterials' PTT (described in section 3) and those from PDT (described above), each regimen can potentiate the other, making injectable hydrogels for combinatorial photodynamic-PTT very appealing. On one hand, photothermal heating can increase the blood

Table 1 Injectable hydrogels for PTT mediated by nanomaterials

Hydrogel components	Modality	Tumor model	Administration route	Hydrogel volume	Laser parameters	Therapeutic outcome	Ref.

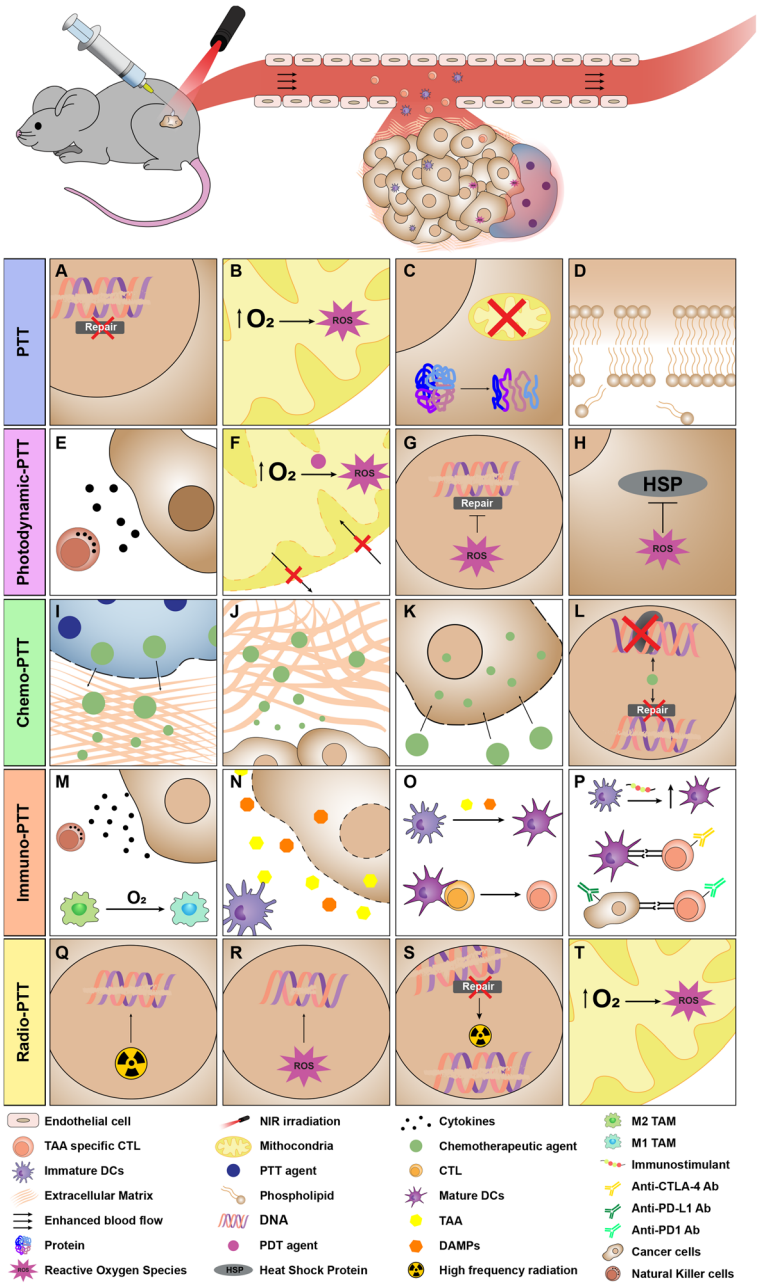

Fig. 2 Schematic representation of therapeutic strategies based on injectable hydrogels incorporating nanomaterials aimed at cancer PTT and respective combinatorial-PTT approaches. (A–D) Main mechanism involved in injectable hydrogel PTT. (A) Inhibition of the DNA repair mechanisms induced by temperature increase. (B) ROS formation after the photothermally triggered tumor oxygenation. (C) Protein denaturation and mitochondria dysfunction caused by the photothermal heating. (D) Collapse of the cell membrane due to the local hyperthermia. (E–H) Key effects in injectable hydrogel photodynamic-PTT. (E) PDT-induced inflammatory response. (F) Improved tumor oxygenation (consequence of PTT) and production of ROS. Modified mitochondrial permeability prompted by ROS. (G) Affected DNA repair mechanism by the PDT-created ROS. (H) Hindered heat shock protein function by ROS. (I–L) Main events occurring in injectable hydrogel chemo-PTT. (I) Alteration of the hydrogel structure by photothermal heating and increased therapeutic agent release from the hydrogel. (J) Disruption of the extracellular matrix (as a consequence of the temperature increase), resulting in enhanced penetration of nanomaterials/drugs. (K) Photothermally triggered permeabilization of cell membrane leading to an enhanced internalization of the enrolled agents. (L) Affected DNA synthesis and repair mechanisms by chemotherapeutic action. (M–P) Main mechanism involved in injectable hydrogel immuno-PTT. (M) Macrophage polarization from a pro- to an anti-tumoral state due to the photothermally triggered hypoxia relief. Production of a pro-inflammatory response. (N) Photothermally induced release of tumor-associated antigens (TAAs) and damage-associated molecular patterns (DAMPs). (O) The released TAAs are processed by immature dendritic cells (DCs), leading to their maturation (aided by DAMPs) and subsequent priming and activation of cytotoxic T cells. (P) Enhanced DC maturation by the immunostimulants encapsulated in the hydrogels. CTLA-4, PD-L1 and PD-1 blockade by the immune checkpoint inhibitors encapsulated in the hydrogels. (Q–T) Key events taking place in injectable hydrogel radio-PTT. (Q) DNA breakage by ionizing radiation. (R) DNA breakage by the ROS produced after exposure to ionizing radiation. (S) Weakened DNA repair mechanisms (consequence of PTT) favor DNA breakage by ionizing radiation. (T) Photoinduced heat increases tumor oxygenation and improves radiotherapy efficacy.

Amido-modified carbon dots and aldehyde-modified cellulose nanocrystals hydrogel	PTT PDT	B16F10 tumor-bearing mice	i.t.	50 μL	660 nm, 0.22 W cm^{-2}, 20 min	Tumor eradication (4 out of 5)	—	135
TMPyP[a] incorporated into collagen-Au nanoparticles hydrogel	PTT PDT	MCF-7 tumor-bearing mice	i.t.	—	635 nm, 0.17 W cm^{-2}, 10 min (4 h and 12 h after the injection)	Tumor eradication (3 out of 4)	Tumor growth inhibition (PTT) Tumor growth reduction (PDT)	136
ICG incorporated into PPG[b]-PEG and α-cyclodextrin hydrogel	PTT PDT	4T1 tumor-bearing mice	i.t.	100 μL	808 nm, 0.14 W cm^{-2}, 5 min (day 1, 3, 5 and 7)	Tumor eradication (2 out of 5)	Tumor growth reduction (PTT)	137
TMPyP incorporated into AuNPs and collagen hydrogel	PTT PDT	MCF-7 tumor-bearing mice	i.t.	50 μL	635 nm, ≈ 0.170 mW cm^{-2}, 10 min (day 0, 1, 2, 3 and 5)	Tumor eradication (2 out of 4)	—	138
BSA[c]-coated MoS_2 nanoflakes incorporated into oxidized sodium alginate and hydroxypropyl chitosan hydrogel	PTT PDT	4T1 tumor-bearing mice	i.t.	50 μL	808 nm, 3 W cm^{-2}, 10 min (days 1, 3, 5, and 7)	Tumor growth reduction	—	139
Ag_2S quantum dots and PTX[d] incorporated into $PC_{10}A$ based hydrogel	PTT Chemotherapy	SKOV3 tumor-bearing mice	i.t.	100 μL	808 nm, 2.5 W cm^{-2}, 10 min	Tumor eradication	Tumor growth reduction (PTT) Tumor growth reduction (chemo)	140
DOX incorporated into Pd nanosheets and thiolated PEG (4-arm) hydrogel	PTT Chemotherapy	4T1 tumor-bearing mice	i.t.	—	808 nm, 0.6 W cm^{-2}, 10 min	Tumor eradication	Tumor growth reduction (PTT) Tumor growth reduction (chemo)	141
DOX incorporated into polyacrylamide, phytic acid and PDA hydrogel	PTT Chemotherapy	SW620 tumor-bearing mice	i.t.	—	808 nm, 0.75 W cm^{-2}, 6 min	Tumor eradication	Tumor growth reduction (PTT) Tumor regression (chemo)	142
PTX-loaded OSPC[e]-based micelles and PEGylated Au nanorods incorporated into poly F127-based hydrogel	PTT Chemotherapy	Hepatocellular carcinoma-bearing mice	i.t.	—	808 nm, 2 W cm^{-2}, 10 min	Tumor eradication	Tumor growth reduction (PTT) Tumor growth reduction (chemo)	143
DOX loaded TPP[f]- and PHBA-functionalized AuMSN[g] and tyramine-HA hydrogel (HRP[h] as catalyzer)	PTT Chemotherapy	MGC-803 tumor-bearing mice	i.t.	100 μL	808 nm, 1 W cm^{-2}, 10 min	Tumor eradication	Tumor regression (PTT) Tumor regression (chemo)	144
DOX and Au/Ag nanorods incorporated into alginate/Ca^{2+} hydrogel	PTT Chemotherapy	A549 tumor-bearing mice	i.t.	50 μL	1064 nm, 1 W cm^{-2}, 10 min (twice)	Tumor eradication (4 out of 5)	Tumor growth reduction (PTT) Tumor growth reduction (chemo)	145
DOX loaded hollow Au nanoshells incorporated into $PC_{10}A$ based hydrogel	PTT Chemotherapy	HepG2 tumor-bearing mice	i.t.	100 μL	808 nm, 2 W cm^{-2}, 9 min	Tumor eradication (4 out of 6)	Tumor growth reduction (PTT) Tumor growth reduction (chemo)	146
PEGylated[i] IDT-BTzTD[j] nanodots and DOX incorporated into agarose hydrogel	PTT Chemotherapy	4T1 tumor-bearing mice	i.t.	100 μL	808 nm, 0.75 W cm^{-2}, 10 min	Tumor regression	Tumor growth reduction (chemo)	147
PB nanoparticles and DOX incorporated into PEI-NIPAM-nanosized cellulose, alginate and chitosan hydrogel	PTT Chemotherapy	MCF-7 tumor-bearing mice	s.c.	200 μL	808 nm, 1.0 W cm^{-2}, 30 min (every 2 days, a total of 3 times)	Tumor regression	—	139
DOX incorporated into Au nanobipyramids, Pt nanoclusters and 4 arm-PEG hydrogel	PTT Chemotherapy	4T1 tumor-bearing mice	i.t.	—	808 nm, 0.5 W cm^{-2}, 10 min	Tumor regression	Tumor growth reduction (PTT) Tumor growth reduction (chemo)	148
Bi_2S_3 nanodots and Sorafenib incorporated into gellan gum hydrogel	PTT Chemotherapy	4T1-Luc tumor-bearing mice	i.t.	100 μL	808 nm, 1 W cm^{-2}, 5 min	Tumor regression	Tumor growth reduction (PTT) Tumor growth reduction (chemo)	149

flow in the irradiated area, improving tumor oxygenation and hence boosting the production of ROS by the photosensitizers.[179,180] On the other hand, the ROS produced during PDT can hinder the function of heat shock proteins which are overexpressed by cancer cells and protect them against the heat-induced damage generated in PTT.[13,181] In an ideal situation, both the photothermal nano-agent and the photosensitizer would be responsive to the same wavelength of NIR light, enabling a straightforward single-irradiation treatment.[12,13] When these agents have very distinct optical properties (*i.e.*, the wavelengths of their maximum absorption are distinct), sequential irradiation with lasers emitting light at different wavelengths is required.[12,13,182]

Sun *et al.* prepared an injectable hydrogel by mixing collagen and $AuCl_4^-$ that achieved gelation through electrostatic interactions.[136] In this process, Au nanoparticles (AuNPs) are simultaneously formed in the hydrogel's matrix. In addition, the water-soluble photosensitizer meso-tetra(*N*-methyl-4-pyridyl) porphine tetrachloride (TMPyP) was also included in the hydrogel matrix.[136] By using 635 nm laser light (0.17 W cm^{-2}, 10 min; at 4 h and 12 h after the injection), the intratumorally injected hydrogel incorporating AuNPs and TMPyP (combinatorial photodynamic-PTT) could eradicate the breast tumors in 3 out of 4 mice (Fig. 3). On the other hand, the stand-alone PTT could only promote the elimination of the breast tumor in 1 mouse, while the stand-alone PDT only reduced the tumor's growth.[136]

4.2. Injectable hydrogels for cancer chemo-PTT

The use of injectable hydrogels for the co-delivery of nanophotothermal agents and chemotherapeutics has also been extensively researched (Table 2). Depending on the water solubility of the chemotherapeutic agents, these can either be incorporated into the hydrogel's hydrophilic network or loaded in the hydrophobic regions of the photothermal nanoagents.[56] Another strategy for loading hydrophobic chemotherapeutics in injectable hydrogels relies on the introduction of hydrophobic moieties (*e.g.*, amphiphilic polymers[183]) or molecules capable of forming complexes (*e.g.*, cyclodextrins[183]) in the hydrogel matrix.[56]

The local delivery of chemotherapeutic drugs using injectable hydrogels is more controlled/sustained and shields healthy tissues from possible side effects.[53,72] Furthermore, the photothermal heating of nanomaterials can (i) disrupt the extracellular matrix and cell membrane, boosting the penetration and internalization of chemotherapeutic drugs, and (ii) interfere with the structural network of some hydrogels (thermo-responsive), stimulating the chemotherapeutics' release (Fig. 2I–L).[10,184]

Zhou and co-workers prepared AuNPs coated with a mesoporous silica shell that were loaded with DOX and functionalized with triphenylphosphine.[144] Upon injection, the phenolic groups of this nanostructure could react covalently with tyrosine-HA (reaction catalyzed by horseradish peroxidase), creating an *in situ*-forming hydrogel.[144] The release of DOX from this hydrogel was responsive to hyaluronidase-mediated degradation and to NIR light-induced photothermal heating. When

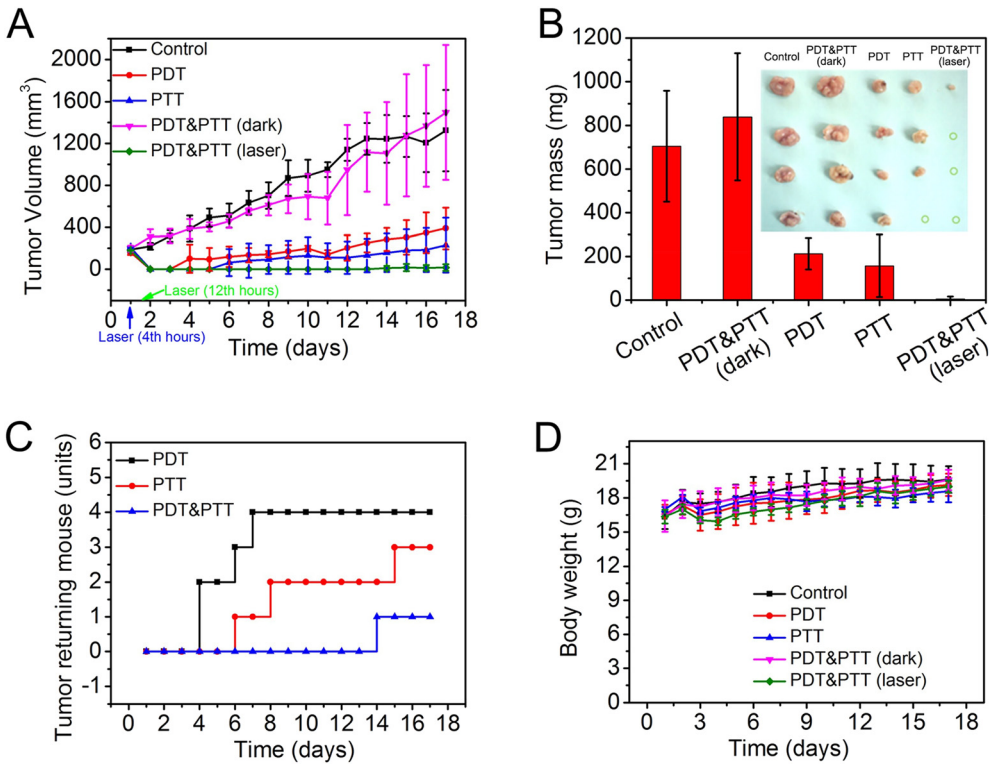

Fig. 3 *In vivo* combinatorial PTT–PDT mediated by collagen-based injectable hydrogels incorporating AuNPs and TMPyP. Tumor volume (A), tumor mass (B), tumor recurrence (C) and body weight (D) after the various treatments. Control: collagen solution and laser irradiation (635 nm, 0.17 W cm^{-2}, 10 min at 4 h and 12 h after injection); PDT: TMPyP solution and laser irradiation; PTT: collagen and AUNPs hydrogel with laser irradiation; PDT&PTT (dark): collagen and AUNPs hydrogel incorporating TMPyP; PDT&PTT (laser): collagen and AUNPs hydrogel incorporating TMPyP with laser irradiation. tested *in vivo*, the chemo-PTT mediated by this hydrogel prompted tumor eradication, while the stand-alone therapies (hydrogel PTT or hydrogel chemotherapy) only induced tumor regression (Fig. 4).[144]

In another work, Jiang *et al.* developed an injectable hydrogel based on the chemical crosslinking occurring between palladium nanosheets (PTT agent) and the thiol pendant groups of branched 4-arm PEG, that also incorporated DOX.[141] This hydrogel mediated a sustained delivery of DOX, the amount of released drug being augmented upon NIR laser irradiation. When tested *in vivo*, the DOX-loaded palladium nanosheets-PEG hydrogel in combination with NIR light (808 nm, 0.6 W cm^{-2}, 10 min) induced breast tumor eradication. In contrast, the stand-alone PTT (palladium nanosheets-PEG hydrogel plus NIR light) could reduce tumors' growth, while the stand-alone chemotherapy (DOX-loaded palladium nanosheets-PEG hydrogel) had a weak therapeutic outcome, being very similar to the control.[141]

4.3. Injectable hydrogels for cancer immuno-PTT

In general, therapeutic approaches based on the use of injectable hydrogels incorporating nanomaterials aimed at cancer PTT are not effective towards metastases nor prevent tumor's recurrence.[185] However, the photothermal heating triggers some events which, aided by immunotherapeutic agents (*e.g.*, immunostimulants, immune checkpoint inhibitors), can lead to the establishment of anti-metastatic cytotoxic T-cell responses and the creation of immune memory.[186–188]

In fact, the local photothermal heating *per se* can (i) induce the release of tumor-associated antigens (TAA) and damage-associated molecular patterns (DAMPs) from cancer cells, (ii) enhance the blood flow into the tumor zone, relieving tumor hypoxia and thus driving macrophages' polarization from a pro- to an anti-tumoral state, and (iii) generate a pro-inflammatory response.[187,189–191] Subsequently, the released TAA can be processed by antigen-presenting cells (*e.g.*, dendritic cells), paving the way for the priming and activation of cytotoxic T cells.[192] The TAA-primed cytotoxic T cells can then potentially mediate the elimination of local and metastasized tumors. In this process, immune memory may also be established, being crucial for the prevention of a tumor's recurrence.[193] To further boost these processes, the injectable hydrogels can be loaded with (i) immunostimulants (*e.g.*, toll-like receptors agonists) to enhance dendritic cell maturation, and (ii) immune checkpoint inhibitors (*e.g.*, CTLA-4 and PD-1/PD-L1 blockers, IDO1 inhibitors) to abolish the immunosuppressive interactions occurring in the tumor microenvironment (Fig. 2M–P).[194]

In a recent study, Revuri *et al.* developed an injectable hydrogel using Pluronic F127 and HA that incorporated bovine

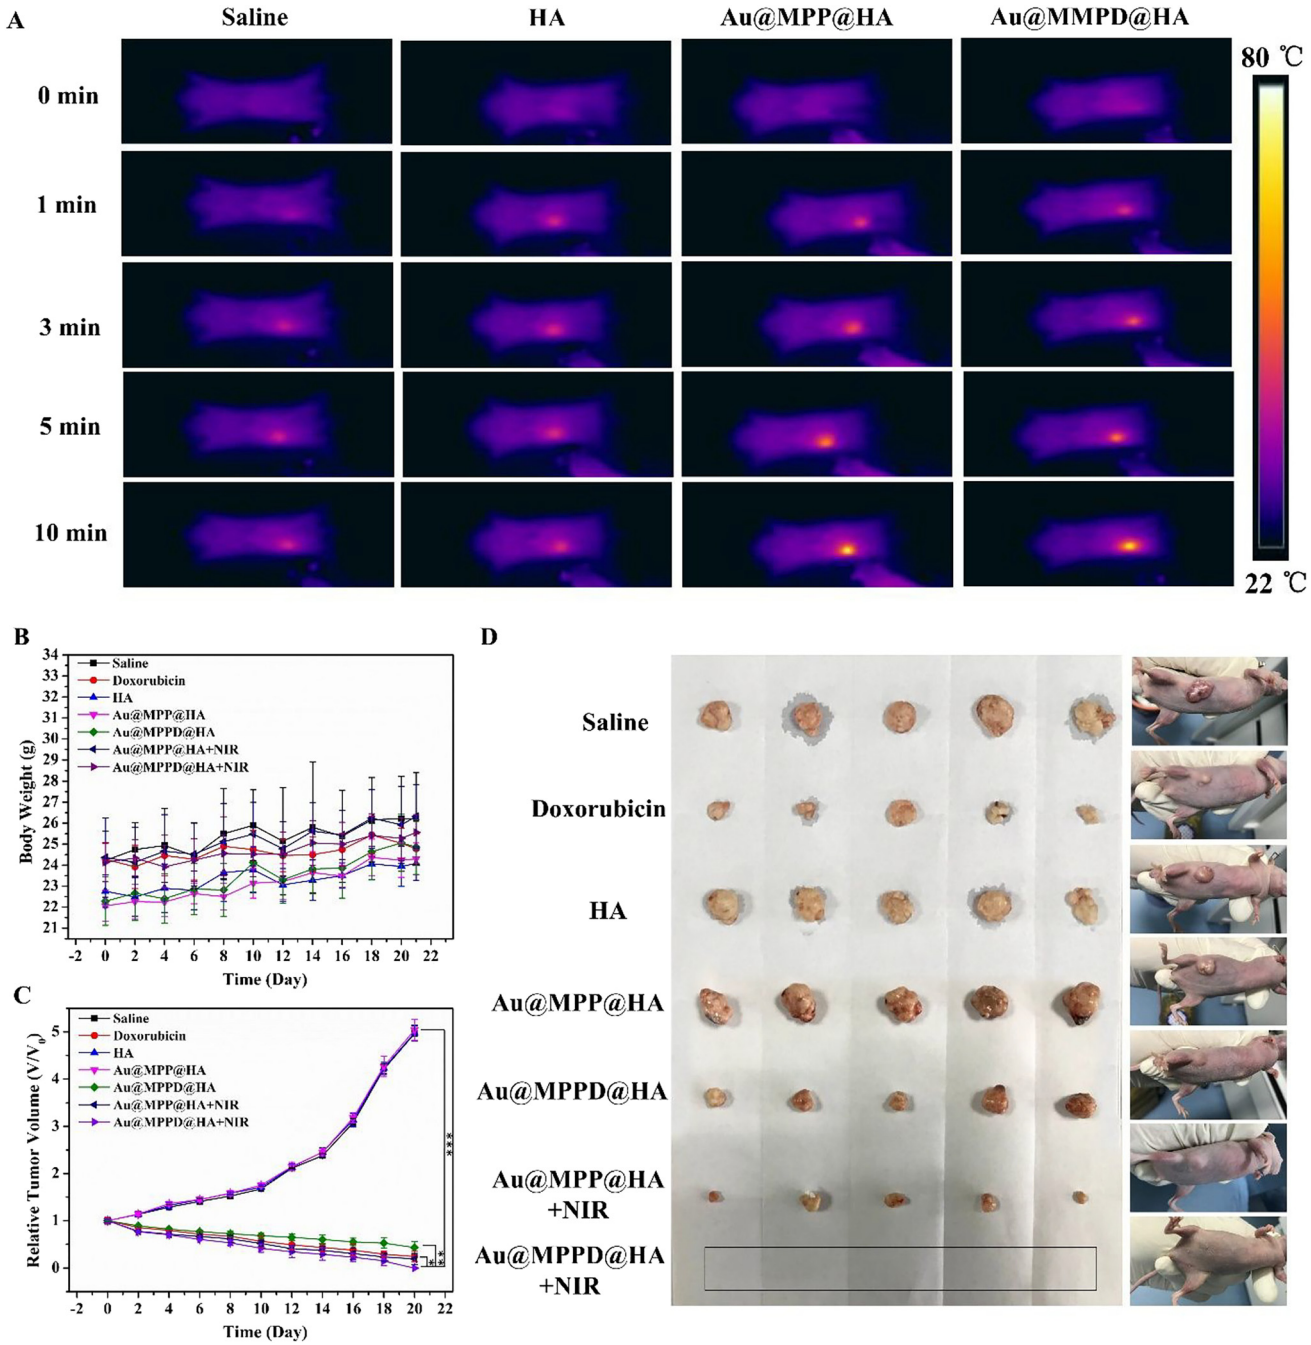

Fig. 4 *In vivo* combinatorial chemo-PTT mediated by an injectable hydrogel based on tyrosine-HA and DOX loaded TPP-AuMSN. Thermographic images of mice after intratumoral administration of the formulations and exposure to NIR irradiation (808 nm, 1 W cm^{-2}) (A). Body weight of the mice after each treatment (B). serum albumin modified-MnO_2 nanoparticles (BSA-MnO_2 nanoparticles) and resiquimod as photothermal and immunostimulating agents, respectively.[169] The assembly of this injectable hydrogel was based on the thermo-responsive behavior of Pluronic F127, which upon heating to body temperature underwent a sol–gel transition (HA was used to improve the hydrogel's mechanical strength).[169] This formulation was then injected into primary tumors in mice, followed by NIR irradiation (808 nm, 2 W cm^{-2}, 10 min), while the secondary tumors were not directly treated (Fig. 5). The immuno-PTT mediated by this injectable hydrogel could inhibit the growth of the primary tumor and reduce the growth of the secondary

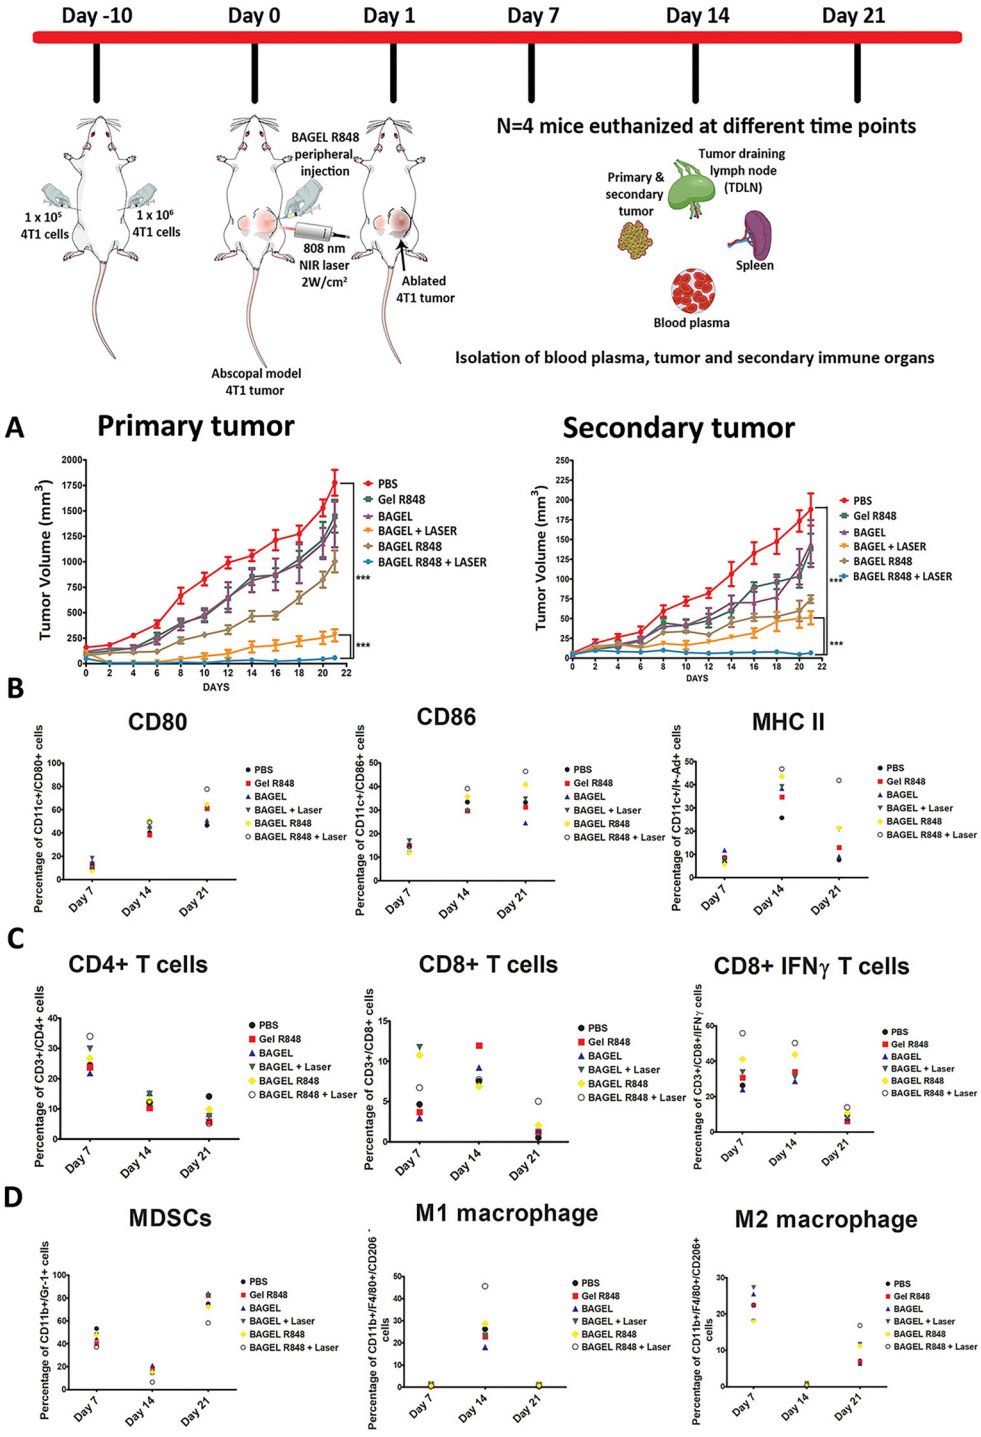

Fig. 5 *In vivo* immuno-PTT mediated by an injectable hydrogel of HA-Pluronic F127 incorporating BSA-MnO_2 nanoparticles and resiquimod. Volume of the primary and secondary tumors (A). tumor. Such effects were correlated with the ability of this treatment to prompt higher levels of matured dendritic cells and activated cytotoxic T cells at the secondary tumor sites.[169]

In another work, Zhang *et al.* produced an injectable hydrogel using *N*-fluorenylmethoxycarbonyl diphenylalanine and poly-L-lysine grafted with thiol-groups, that incorporated bili-

verdin (photothermal agent) and thymopentin (immunomodulatory peptide).[171] This hydrogel system presented a shear-thinning/self-healing behavior, being assembled through electrostatic and hydrophobic interactions, π–π stacking and disulfide bonds. *In vivo*, the immuno-PTT mediated by this injectable hydrogel led to tumor regression, while the stand-alone therapies (hydrogel PTT or hydrogel immunotherapy) only prompted a reduction of the tumor's growth. The hypoxia relief, improved dendritic cell maturation, and enhanced T-cell recruitment mediated by the combinatorial treatment contributed to this therapeutic outcome.[171]

4.4. Injectable hydrogels for cancer radio-PTT

Injectable hydrogels aimed at cancer PTT can also be combined with high-frequency radiation (*e.g.*, X-rays, gamma rays) with the intent to achieve a greater therapeutic outcome.[13] Such radio-photothermic application can also be performed by incorporating photothermal nano-agents and radionuclides (*e.g.*, ^{131}I) into the injectable hydrogels.[195] In this process, radiosensitizers (*e.g.*, SmacN7) may also be included to further boost the therapeutic outcome.[178,195]

On one hand, the delivery of radionuclides/radiosensitizers using injectable hydrogels into the tumor tissue can contribute to protecting healthy cells from the ionizing radiation.[196,197] The ability of the produced photoinduced heat to improve tumor oxygenation also plays an important role in improving the therapeutic outcome (radiotherapy displays lower efficacy in hypoxic environments).[13,198] Moreover, such temperature increase can also weaken the DNA repair mechanism, being crucial to prevent the repair of the DNA double-strand breaks caused by radiotherapy.[100] On the other hand, the higher penetration depth of radiotherapeutic approaches can counterbalance the limitation of PTT in treating deep-seated tumors (NIR light has limited penetration depth) (Fig. 2Q–T).[199]

Wang and co-workers developed an injectable thermo-responsive hydrogel composed of agarose incorporating Prussian blue nanoparticles, which was combined with NIR and high-frequency radiation, for breast cancer radio-PTT.[173] Besides acting as the photothermal nano-agent, the Prussian blue nanoparticles also decomposed H_2O_2 to produce O_2, counteracting tumor hypoxia and acting as a radiosensitizer.[173] After administration of this formulation, the tumor area was irradiated with NIR light (808 nm, 1 W cm^{-2}, 5 min) and high-energy radiation (2 Gy, 5 min, at 6 h post-PTT). This treatment resulted in tumor regression. In contrast, the application of stand-alone therapies only induced a reduction in tumor growth (Fig. 6).[173]

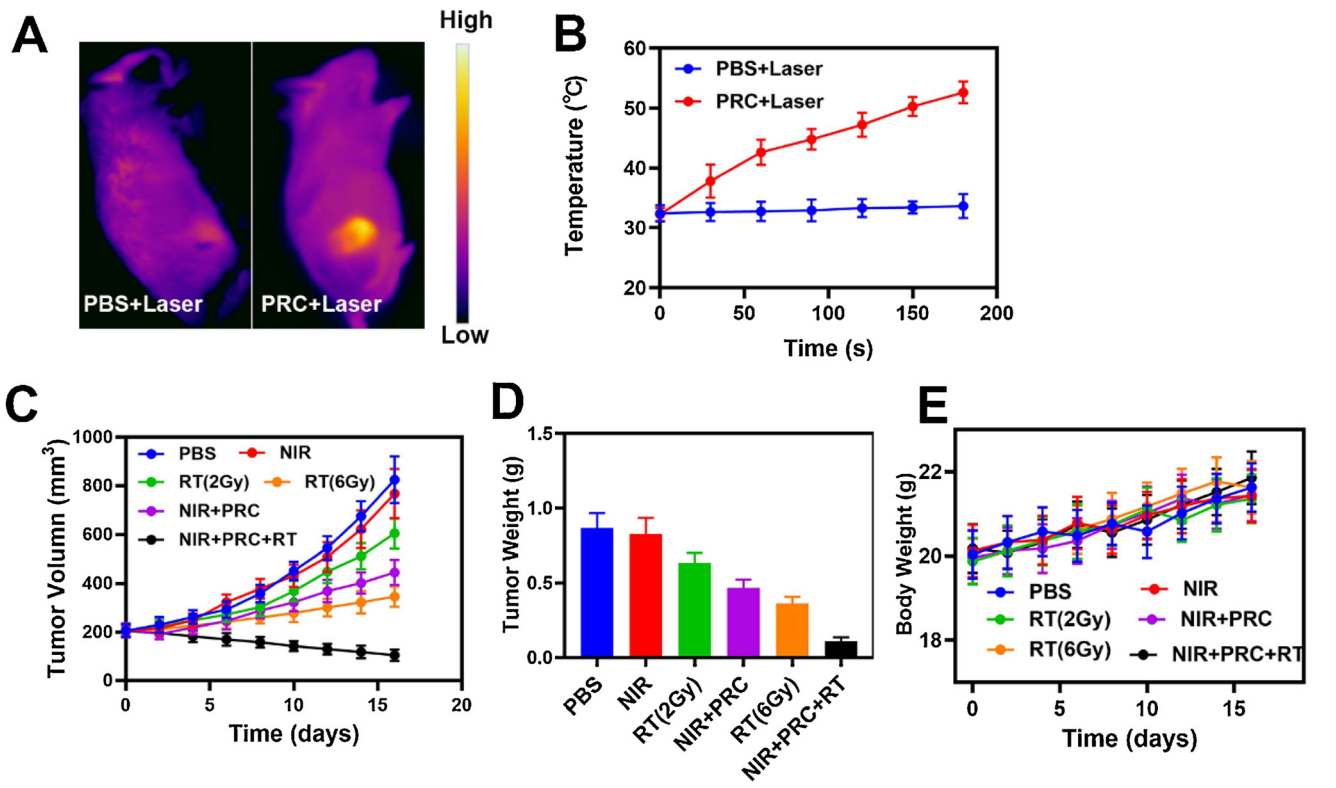

Fig. 6 *In vivo* radio-PTT mediated by an agarose-based injectable hydrogel incorporating Prussian blue nanoparticles. Thermal images of mice (A) and temperature of the tumor zone (B) after exposure to phosphate-buffered saline or agarose hydrogel incorporating Prussian blue nanoparticles and NIR light (808 nm, 1 W cm^{-2}, 5 min). Tumor volume (C), tumor weight (E) and body weight (D) of mice after the different treatments. NIR: NIR light (808 nm, 1 W cm^{-2}, 5 min); RT (2 Gy): high-energy radiation (2 Gy, 5 min); RT (6 Gy): high-energy radiation (6 Gy, 5 min); NIR + PRC: Prussian blue NPs-agarose hydrogel and NIR light; NIR + PRC + RT: Prussian blue NPs-agarose hydrogel, NIR light and high-energy radiation (2 Gy). 5. Conclusion and remarks for the future

In this review, the application of injectable hydrogels for mediating nanomaterials' cancer combinatorial-PTT was analyzed.

The use of injectable hydrogels for the local delivery of nanomaterials and/or other agents directly into the tumor ensured appropriate levels of these compounds at the target site while sparing other tissues from off-target toxicity. This is crucial to overcome the limitations associated with the systemic administration of anti-cancer therapies. These injectable hydrogels have been assembled using a myriad of natural (*e.g.*, chitosan, alginate, cellulose, HA) and synthetic (*e.g.*, Pluronic F127, PC10A, PEG) polymers. In this regard, the polymers' selection was revealed to be of utmost importance since it affected the properties of the attained injectable hydrogels and also directed the hydrogel's crosslinking mechanism (physical, chemical or hybrid). Just as important, injectable hydrogels were also designed to be responsive to different external and internal stimuli (*e.g.*, pH, enzymes, magnetic field, light), which assisted in the assembly/disassembly process, degradation, and release of the loaded nanomaterials/therapeutic agents, ultimately providing a path for a more controlled therapy.

The standalone use of injectable hydrogels incorporating nanomaterials aimed at cancer PTT has proved to be capable of good *in vivo* outcomes. In this regard, some hydrogel formulations were capable of inducing tumor eradication or regression after NIR laser irradiation. However, the vast majority of the analyzed injectable hydrogels containing nanomaterials intended for PTT only prompted a reduction of the tumor's growth (Table 1). Such outcome is likely multifactorial, highlighting the limitations of standalone PTT (*e.g.*, penetration limit of NIR light, heterogeneous heat transfer in the tumor mass).[199,200]

In order to improve the therapeutic outcome, injectable hydrogels containing photothermal nano-agents were combined with other modalities: PDT, chemotherapy, immunotherapy, radiotherapy. These combinatorial approaches aimed to overcome the limitations of PTT and of the other standalone therapies, leading to synergistic outcomes. Among the different combinatorial strategies analyzed (Table 2), injectable hydrogels containing nanomaterials for PTT combined with PDT and chemotherapy were by far the most explored. In fact, the application of injectable hydrogels for combinatorial-PTT led to an increase in the levels of tumor eradications and regressions. In these works, the respective standalone therapies mostly prompted a reduction in the tumor's growth, thus emphasizing the enhanced outcome that arises from the injectable hydrogel combinatorial-PTT.

The number of publications related to injectable hydrogels for cancer PTT and combinatorial-PTT has clearly been growing in the last 5 years. So far, several clinical trials using injectable hydrogels for cancer-related applications have been proposed/completed (*e.g.*, ClinicalTrials.gov Identifiers: NCT03713021, NCT01538628, NCT03125226, NCT05224869). Furthermore, the use of hydrogels in numerous biomedical-related applications has increased, their market being estimated to generate revenues of 31.4 billion USD by 2027.[201,202]

Notwithstanding, in order to accelerate the translation of injectable hydrogels, it is crucial to address the issues related to their sterilization, scale-up and stability during storage. In this regard, the incorporation of anti-microbial agents into the hydrogels (*e.g.*, silver nanoparticles, chitosan) may reduce the risk of infection after their injection. Additionally, the use of non-toxic elements in the injectable hydrogels' assembly may accelerate the laborious and time-consuming purification steps. The fabrication of the injectable hydrogels' precursor solutions in state-of-the-art equipment may also ease the scale-up processes. In turn, strictly controlling the handling and storage conditions (*e.g.*, temperature, moisture, pH, exposure to radiation) of the injectable hydrogels and respective precursor solutions is fundamental to improving their stability during storage.

Moreover, the gelation time of some injectable hydrogels could be improved, since this parameter is crucial to efficiently confine the therapeutics in the tumor zone. In this context, the optimization of the polymer's features (*e.g.*, molecular weight, polydispersity, viscosity) and crosslinking strategies (*e.g.*, crosslinking degree, combination of physical and chemical crosslinking) may endow injectable hydrogels with an even faster gelling time that will prevent leakage of the therapeutics to undesired sites. Another challenge is related to the release kinetics of the loaded therapeutic agents from the injectable hydrogels. In this regard, the production of hierarchically organized injectable hydrogel systems with logical and scheduled release through layered degradation is an appealing strategy.

Finally, appropriate selection of the biological models/assays for screening the efficacy and safety of the injectable hydrogels for cancer combinatorial-PTT is also of critical importance. Besides the classical *in vitro* models, the adoption of advanced screening toolsets based on 3D cultures (*e.g.*, spheroids[203]) or organ-on-a-chip[204] could enable a better *in vitro* evaluation of the injectable hydrogels' performance. Such screening using these state-of-the art models could contribute to the discovery of formulations with greater chances of performing *in vivo* as well as the ability to discard earlier those that will yield unsatisfactory results.

On the other hand, the long-term biodegradability of the injectable hydrogels for combinatorial-PTT is also a parameter that deserves further investigation and fine-tuning. Firstly, most studies dedicated to this matter only analyze the short-term biocompatibility in small animal models (*e.g.*, mice). In this regard, assessing the long-term biocompatibility of the injectable hydrogels is of utmost importance for their future clinical translation. Furthermore, it is also crucial to perform such analyses in both small- and large-scale animal models (*e.g.*, non-human primates). In turn, the biocompatibility of the injectable hydrogels may also be enhanced through the use of biodegradable materials in their formulation, such as natural polymers or synthetic polymers engineered with bio-

logically labile sub-units. On this subject, favoring the use of photothermal agents that are easily decomposed (*e.g.*, biodegradable nanoparticles loading NIR light-absorbing small molecules) or that are rapidly cleared through renal filtration (*i.e.*, nanostructures with a size below 5 nm) may also contribute to the translation of injectable hydrogels for combinatorial-PTT.

Overall, the continuous investigation of injectable hydrogels for nanomaterials-mediated combinatorial-PTT brings forward the possibility of attaining a multifunctional system for an improved and selective anti-cancer treatment.
