Does a nitrogen matter? Synthesis and photoinduced electron transfer of perylenediimide donors covalently linked to C$_{59}$N and C$_{60}$ acceptors†

Luis Martín-Gomis,a Georgios Rotas,b Kei Ohkubo,c Fernando Fernández-Lázaro,a Shunichi Fukuzumi,*c,d Nikos Tagmatarchis*b and Ángela Sastre-Santos*a

The first perylenediimide (PDI) covalently linked to an azafullerene (C$_{59}$N) is described. PDI–C$_{59}$N and PDI–C$_{60}$ dyads where PDI acts as an electron-donor moiety have been synthesized by connection of the balls to the PDI 1-bay position. Photoexcitation of the PDI unit in both systems results in formation of the charge-separated state by photoinduced electron transfer from the singlet excited state of the PDI moiety to the C$_{59}$N or to the C$_{60}$ moiety. The charge-separated state has a lifetime of 400 ps in the case of PDI–C$_{59}$N and 120 ps for the PDI–C$_{60}$ dyad in benzonitrile at 298 K. This result has significant implications for the design of organic solar cells based on covalent donor–acceptor systems using C$_{59}$N as an electron acceptor, indicating that longer-lived charge-separated states can be attained using C$_{59}$N systems instead of C$_{60}$ systems.

Introduction

The seeking for efficient molecular systems, based on the covalent combination of suitable and versatile building blocks, capable to mimic the photoinduced electron transfer that naturally occurs in photosynthesis, has been a constant in material science.† In a simplistic definition, a molecular system which combines an electron-acceptor moiety with an electron-donor counterpart, able to be excited by the action of light, can be considered as a potential photosynthetic system, and therefore useful for photovoltaic applications. [60] Fullerene, due to its extraordinary electron-acceptor character and its fascinating chemical versatility, has been one of the most utilized electron-acceptor building blocks² for that purpose and, thus, several efficient artificial photosynthetic [60] fullerene-based systems have been described, using different chromophores as photoexcitable electron-donor counterparts.³ Performances of these donor–acceptor materials can be improved by selecting an appropriate electron-donor counterpart, but also by replacing one or more carbon atoms of the fullerene cage by heteroatoms, affording the so-called heterofullerenes.⁴ The substitution of a tetravalent carbon atom of the three dimensional network by a trivalent nitrogen atom is one of the most interesting alterations. This simple modification leads to azafullerene C$_{59}$N, a fullerene-based building block with an improved electron-acceptor character, when it is compared to that of pristine C$_{60}$ fullerene.⁵ A number of different azafullerene-based donor–acceptor covalent compounds have been previously described, showing interesting photophysical properties that make them ideal candidates to be incorporated in organic photovoltaic devices. Hirsch et al. described the synthesis of an azafullerene-ferrocene dyad that shows strong electronic coupling between the ferrocene and azafullerene moieties in the ground state.⁶ Additional C$_{59}$N-based dyads carrying photoactive units such as porphyrin⁷ and pyrene⁸ were also prepared. More recently, azafullerene–electron-donor dyads, using phthalocyanine⁹ and corrole¹⁰ units, have been reported to undergo photoinduced electron transfer upon selective irradiation of the electron-donor moiety.

On the other hand, perylenediimides (PDI) comprise an outstanding family of perylene derivatives that, due to an extreme synthetic versatility and an easily tunable electronic character, have become one of the most promising classes of molecular materials in organic photovoltaic devices.¹¹ In this context, we can find only a few examples where PDI derivatives...
have been successfully employed as an electron-donor moiety in fullerene-based systems, eventually undergoing photo-induced electron and/or energy transfer.\textsuperscript{12}

Here we present the synthesis, characterization and photo-physical properties of a new photoexcitable molecular system, consisting of an electron-donor PDI moiety, carrying a pyrroldinyl substituent in the 1-bay position, which also acts as a linker to the C\textsubscript{59}N counterpart (Scheme 1). The obtained donor-acceptor PDI-C\textsubscript{59}N dyad 1, upon selective excitation of the PDI subunit in benzonitrile, shows efficient intramolecular photoinduced electron transfer, generating a 400 ps-lived charge-separated state (CSS). Together with two covalently linked porphyrin-C\textsubscript{59}N dyads,\textsuperscript{7} this is the longest CSS lifetime value obtained so far for a C\textsubscript{59}N-based donor-acceptor dyad in a polar solvent. Moreover, in order to study the effect of the nitrogen atom on the photophysics, the analogous PDI-C\textsubscript{60} dyad 2 (Scheme 1) was synthesized, as reference material, obtaining a 3-times shorter CSS lifetime than for the PDI-C\textsubscript{59}N dyad 1, thus, highlighting the role of nitrogen in the photoinduced electron-transfer processes.

### Synthesis and characterization

Initially, PDI-C\textsubscript{59}N and PDI-C\textsubscript{60} dyads 1 and 2 were synthesized as described in Scheme 1. Firstly, (R)-1-(2'-hydroxymethyl-pyrrolidin-N-yl)PDI 3 was obtained upon nucleophilic aromatic substitution on \(N,N\textsuperscript{-}di(2\text{-ethylhexyl})\text{-}1\text{-bromoperylene-3,4,9,10-tetracarboxy diimide}\) by (R)-2-hydroxymethylpyrrolidine in 51% yield. Then, the esterification reaction of PDI-based 3 with azafullerencadic acid 4\textsubscript{a}\textsuperscript{14} and PDI-based 3 was followed, affording in 43% yield PDI-C\textsubscript{60} dyad 2. Furthermore, PDI derivative 6 was also synthesized in 75% yield, through an acylation of 3 with acetic anhydride in acidic media, in order to be used as a reliable reference to evaluate optical, electrochemical and photophysical properties.

All new compounds were fully characterised using standard analytical techniques such as \(^1\text{H}\) and \(^{13}\text{C}\) NMR, HR-MS, FT-IR, electronic absorption and photoluminescence. Fig. 1 compares

![Scheme 1](image)

**Scheme 1** Synthetic routes for preparing PDI-C\textsubscript{59}N 1 and PDI-C\textsubscript{60} 2 dyads as well as PDI-based reference material 6.

![Fig. 1](image)

**Fig. 1** Partial \(^1\text{H}\) NMR (9.30–8.00 ppm) spectra of (a) PDI-based reference material 6, (b) PDI-C\textsubscript{60} 2, and (c) PDI-C\textsubscript{59}N 1.
the aromatic region of the $^1$H NMR spectra for 1, 2 and 6 in CDCl$_3$ as solvent. Taking as reference the C1 of the PDI core (the substituted one), and comparing the signals of analogous hydrogens in compounds 1, 2 and 6, it is worth noting that the chemical displacement of the nearby hydrogens (H$^2$, H$^{11}$ and H$^{12}$) is significantly shifted in dyad’s spectra, while the contrary trend is observed in the displacement of H$^3$, H$^6$, H$^7$ and H$^8$. For example, the H$^2$ signal goes from 8.69 to 9.19 and 9.18 ppm (in 2 and 1 respectively), while H$^6$ goes from 8.45 to 8.40 ppm. Furthermore, the fullerene influence is slightly larger when C$_{59}$N is present instead of C$_{60}$, and it can be recognized in the H$^{12}$ displacement, which changes from 8.11 ppm in 6, to 8.29 and 8.40 ppm in dyads 2 and 1, respectively. Fig. 2 shows the aliphatic regions of the spectra, where some differences can also be found due to the presence of the covalently attached fullerene. For example, the signals corresponding to the hydrogens labeled as H$^H$, H$^C$ and H$^E$, which appear as broad signals in the spectrum of PDI-based 6, split into two in the corresponding spectra of PDI-fullerene dyads 1 and 2. All these differences in the $^1$H NMR spectra of dyads and reference material can be explained by considering the electron-withdrawing character of the fullerene sphere, which is more intense in the case of C$_{59}$N as compared with C$_{60}$, and also assuming a pseudo-fixed molecular conformation in PDI-fullerene dyads caused by an electrostatic interaction between the PDI and the fullerene moiety including a concave–convex interaction$^{3,15}$ that causes a different influence of the sphere on the chemical shift of the pyrrolidine-linker geminal protons. HR MALDI-TOF (negative mode) experiments clearly confirm the structure of PDI-C$_{59}$N and PDI-C$_{60}$ dyads 1 and 2 respectively. Fig. 2 shows the partial $^1$H NMR (5.50–1.60 ppm) spectra in CDCl$_3$ as solvent of (a) PDI-based reference material 6, (b) PDI-C$_{60}$ 2, and (c) PDI-C$_{59}$N 1.

Photophysical and electrochemical properties

Fig. 3 shows the overlapped UV-vis spectra of dyads 1 (black line) and 2 (blue line) and C$_{60}$ 5a, C$_{59}$N 4b and PDI 6 as reference compounds using benzonitrile as solvent. The absorption spectra of PDI-C$_{59}$N 1 and PDI-C$_{60}$ 2 dyads are characterised by two sets of absorption maxima around 430 and 638 nm. The band centered at 430 nm can be attributed to transitions 0–0 in the PDI species,$^{16}$ while the one centred at 638 nm consists of a broad charge transfer (CT) band that usually appears in bay amino-substituted PDI compounds. The latter band appears as a consequence of an electron transfer between the electron-donor pyrrolidine and the electron-acceptor PDI units,$^{17}$ and therefore is very sensitive to changes in the electronic character of the entire molecule. When those spectra are compared to the absorption profile of reference compound PDI 6, some differences can be found. One of these differences, directly related to the electronic interaction between the electroactive moieties, is a bathochromic displacement of the band centered at 632 nm, which now appears at 638 nm in both PDI-C$_{60}$ and PDI-C$_{59}$N. This fact reveals the electronic influence of the fullerene sphere on the perylene subunit in the ground state, as it has been already pointed out in the comparison of $^1$H NMR spectra (cf. Fig. 1 and 2).

On the other hand, Fig. 4 shows the fluorescence emission spectra of PDI-C$_{59}$N 1 and PDI-C$_{60}$ 2 dyads, when selectively excited at 429 nm. As can be seen, the fluorescence spectrum of 6 clearly shows three different emission bands, centered at 480, 512 and 691 nm. When the emission spectra of PDI-C$_{59}$N and PDI-C$_{60}$ dyads 1 and 2 are compared to that of the reference compound, the first and second bands are partially
quenched while the third one is extinguished. The latter is indicative of intra-dyad electronic interactions between the two components of the dyad (i.e., PDI and fullerene) at the excited state. The strong fluorescence quenching of the 691 nm band in both 1 and 2 as compared to 6, supports electron and/or energy transfer as the decay mechanism of the PDI-centred singlet excited state. This effect is slightly more pronounced in the case of PDI-C59N dyad 1 (see inset Fig. 4).

The electrochemical data of PDI-C59N 1 and PDI-C60 2 dyads, as well as 6, 4b and 5b as reference materials for PDI-C59N, and C60, respectively, in benzonitrile using Fc/Fc+ as an internal standard are listed in Table 1 (see differential pulse voltammograms in ESI, Fig. S13†). The measurements for PDI 6 reveal a one-electron oxidation and two one-electron reduction processes centred at 0.55, −1.15 and −1.35 V respectively, while the measurements for fullerene reference compounds show two one-electron reversible reduction processes at −1.01 and −1.42 V. The voltammograms of dyads 1 and 2 are very similar, in spite of the nitrogen atom in dyad 1, and can be considered as a combination of the already mentioned electrochemical processes assigned to PDI and fullerene electroactive moieties. A slight influence of the fullerene sphere (either C59N or C60) over the PDI moiety can be recognised, and it is highlighted by a 20–30 mV anodic displacement of the oxidation wave and a 40 mV cathodic displacement of the second reduction process, which is attributed to the PDI counterpart. As contrary to previous results reported by us,9,10 the similar first reduction values obtained for PDI-C60 and PDI-C59N might come from the use of different solvents. Based on the redox data shown in Table 1 and neglecting the Coulombic interactions, the electrochemical band gap for 1 is calculated as 1.59 eV (1.61 eV for 2).

Femtosecond laser flash photolysis on a deaerated benzonitrile solution of 1 and 2 indicates the formation of a charge-separated state, providing solid evidence for the electron-transfer deactivation mechanism in 1 and 2, after selective excitation of the perylene moiety. The transient absorption spectrum taken at 1 ps after laser pulse irradiation of the absorption band of the PDI moiety at 490 nm exhibits an absorption maximum at 900 nm, which is assigned to the singlet excited state of C59N of PDI-C59N dyad 1 (Fig. 5a). No indication of the PDI singlet excited state was observed in spite of the selective excitation of PDI, indicating that the rate of energy transfer from the singlet excited state of the PDI moiety to the C59N moiety is too fast to be followed even with the use of femtosecond laser flash photolysis (fwhm = 130 fs). Then, electron transfer from PDI to the singlet excited state of C59N takes place to form PDI•−-C59N•+ as the charge-separated state. The transient absorption band decayed with a rate constant of $5.5 \times 10^{10}$ s$^{-1}$ giving rise to an absorption band at $\lambda_{\text{max}} = 1030$ nm due to the C59N•+ radical anion,9,10 which indicates the formation of the charge-separated state. From the decay of the absorption band at 1030 nm, a 400 ps lifetime ($k = 2.5 \times 10^9$ s$^{-1}$) was obtained for the charged-separated state (Fig. 5b), being the first example of a charge-separated state in a donor-acceptor dyad based on PDI and azafullerene.

When benzonitrile was replaced by toluene, the rate constant of charge separation became much larger ($3.9 \times 10^{11}$ s$^{-1}$), whereas the rate constant of charge recombination became smaller ($1.3 \times 10^9$ s$^{-1}$) as shown in Fig. S14 (ESI†). The faster charge separation in toluene than in benzonitrile may result from PDI-C59N-C60) over the PDI moiety can be recognised, and it is highlighted by a 20–30 mV anodic displacement of the oxidation wave and a 40 mV cathodic displacement of the second reduction process, which is attributed to the PDI counterpart. As contrary to previous results reported by us,9,10 the similar first reduction values obtained for PDI-C60 and PDI-C59N might come from the use of different solvents. Based on the redox data shown in Table 1 and neglecting the Coulombic interactions, the electrochemical band gap for 1 is calculated as 1.59 eV (1.61 eV for 2).

Femtosecond laser flash photolysis on a deaerated benzonitrile solution of 1 and 2 indicates the formation of a charge-separated state, providing solid evidence for the electron-transfer deactivation mechanism in 1 and 2, after selective excitation of the perylene moiety. The transient absorption spectrum taken at 1 ps after laser pulse irradiation of the absorption band of the PDI moiety at 490 nm exhibits an absorption maximum at 900 nm, which is assigned to the singlet excited state of C59N of PDI-C59N dyad 1 (Fig. 5a). No indication of the PDI singlet excited state was observed in spite of the selective excitation of PDI, indicating that the rate of energy transfer from the singlet excited state of the PDI moiety to the C59N moiety is too fast to be followed even with the use of femtosecond laser flash photolysis (fwhm = 130 fs). Then, electron transfer from PDI to the singlet excited state of C59N takes place to form PDI•−-C59N•+ as the charge-separated state. The transient absorption band decayed with a rate constant of $5.5 \times 10^{10}$ s$^{-1}$ giving rise to an absorption band at $\lambda_{\text{max}} = 1030$ nm due to the C59N•+ radical anion,9,10 which indicates the formation of the charge-separated state. From the decay of the absorption band at 1030 nm, a 400 ps lifetime ($k = 2.5 \times 10^9$ s$^{-1}$) was obtained for the charged-separated state (Fig. 5b), being the first example of a charge-separated state in a donor-acceptor dyad based on PDI and azafullerene.

When benzonitrile was replaced by toluene, the rate constant of charge separation became much larger ($3.9 \times 10^{11}$ s$^{-1}$), whereas the rate constant of charge recombination became smaller ($1.3 \times 10^9$ s$^{-1}$) as shown in Fig. S14 (ESI†). The faster charge separation in toluene than in benzonitrile may result

**Table 1**: Redox potentials of PDI-C59N 1 and PDI-C60 2 dyads and 6, 4b and 5b as reference materials for PDI-C59N and C60 respectively. The values are versusFc/Fc+ and extracted from differential pulse voltammograms of PhCN solutions containing Bu4NPF6 (0.10 M) as a supporting electrolyte.

from the smaller solvent reorganisation energy of toluene than that of the more polar benzonitrile in the Marcus normal region, where the charge separation becomes faster with decreasing the solvent reorganisation energy of electron transfer. By the same token, the slower charge recombination in toluene than in benzonitrile results from the smaller solvent reorganisation energy of toluene than that of benzonitrile in the Marcus inverted region, where the charge recombination becomes slower with decreasing the solvent reorganisation energy of electron transfer.

On the other hand, a similar transient absorption spectral change was observed for PDI-C60 dyad 2 as shown in Fig. 6a. The transient absorption recorded at 1 ps after femtosecond laser pulse irradiation is assigned to the singlet excited state of C60, indicating that ultrafast energy transfer from the singlet excited state of PDI to the C60 moiety also occurs in PDI-C60. Then, electron transfer from PDI to the singlet excited state of C60 takes place to form the charge-separated state. The rate constant for electron transfer is determined to be $8.6 \times 10^{10}$ s$^{-1}$ from the rise of the absorbance at 1000 nm (inset of Fig. 6b). This rate is slightly faster than that of PDI-C59N (vide supra). The lifetime of the charge-separated state was determined to be 120 ps from the decay of absorbance at 1000 nm as shown in Fig. 6b. It is worth to mention the much shorter lifetime of the CSS in PDI-C60, less than one third of that in PDI-C59N, pointing to the remarkable influence of the nitrogen atom in C59N, which is not explained only by an increased electron-accepting character as the reduction potentials of 1 and 2 indicate. In both cases, the decay of the charge-separated state by back electron transfer yields the ground state rather than the triplet excited state of PDI as indicated by no triplet transient absorption of 1 and 2 in nanosecond laser flash photolysis measurements (Fig. S14 in ES†).

**Experimental**

**General information**

All chemicals were reagent grade, purchased from commercial sources, and used as received, unless otherwise specified. Column chromatography: SiO$_2$ (40–63 mm) TLC plates coated with SiO$_2$ 60F254 were visualized by UV light. 2 and 6 crude products were finally purified by a Combiflash RF chromatography system (Teledyne Technologies, Inc., Thousand Oaks, CA), while 1 crude product was finally purified by preparative HPLC (Japan Analytical Industry Co Ltd, utilising a Buckyprep 20 × 250 column with toluene as eluent at 10 mL min$^{-1}$ flow rate). NMR spectra were measured with a Bruker AC 300. UV/vis spectra were recorded with a Helios Gamma spectrophotometer. Fluorescence spectra were recorded with a PerkinElmer LS 55 Luminescence Spectrometer and IR spectra with a Nicolet Impact 400D spectrophotometer. Mass spectra were obtained from a Bruker Microflex matrix-assisted laser desorption/ionization time of flight (MALDI-TOF).

**tert-Butyl (2,2-[60]fullereny1)acetate 5b** and ethyl (2-azaful-lerenyl)acetate 4b, used as C$_{60}$ and C$_{59}$N reference compounds, respectively, in electrochemistry measurements, were prepared as reported earlier.

**Electrochemistry**

Differential pulse voltammetry measurements were performed in a conventional three-electrode cell using a µ-AUTOLAB type III potentiostat/galvanostat at 298 K, over PhCN deaerated sample solutions (~0.5 mM), containing 0.10 M tetrabutylammonium hexafluorophosphate (TBAP$^+$) as supporting electrolyte. A glassy carbon (GC) working electrode, Ag/AgNO$_3$, reference electrode and a platinum wire counter electrode were employed. Ferrocene/ferrocenium was used as an internal standard for all measurements.

**Synthesis**

**Synthesis of 
$N,N'$-di(2-ethylhexyl)-1-[(R)-2-(hydroxymethyl)-pyrrolidinyl]perylene-3,4,9,10-tetracarboxy diimide (3).** Over a heated solution (90 °C) of (R)-2-(hydroxymethyl)pyrrolidine (500 mg, 4.95 mmol), in NMP (10 ml), 100 mg (0.14 mmol) of $N,N'$-di(2-ethylhexyl)-1-bromoperylene-3,4,9,10-tetracarboxy diimide suspended in 100 ml of NMP were slowly added under Ar atmosphere. When the addition was completed, the mixture was left at 90 °C continuously stirring for 48 h. The crude product was added over 400 ml of NaOH 1 M, vacuum filtered and washed with distilled water, in order to eliminate the undesirable NMP used as solvent. The crude material was finally purified by column chromatography (SiO$_2$, H$_2$→H$_2$-AcOEt 3:1) to obtain 52 mg (51%) of the desired product as a green powder. $^1$H NMR (300 MHz, 25 °C): 8.46 (1H, s, H-PDI), 8.35 (2H, m, 3 × H-PDI), 8.18 (1H, d, $J$ = 8.2 Hz, H-PDI), 8.02–7.89 (2H, m, 2 × H-PDI), 7.55–7.47 (1H, m, 2 × H-PDI), 4.51–4.39 (1H, m, CHN-pyrrolidine), 4.31 (1H, t, $J$ = 12.7 Hz, CHH-Oh), 4.21–4.03 (4H, m, 2 × CH$_2$-N-alkyl chain), 3.98 (1H, t, $J$ = 12.7 Hz, CHH-Oh), 3.57–3.41 (1H, m, CHH-pyrrolidine), 2.30–2.09 (2H, m, CH$_2$-pyrrolidine), 2.07–1.91 (2H, m, CHH-pyrrolidine + CH-alkyl chain), 1.90–1.76 (1H, m, CH-alkyl chain), 1.71–1.59 (2H, m, CHHN-pyrrolidine + CHH-pyrrolidine) 1.54–1.21 (16H, m, 8 × CH$_2$-alkyl chain) and 1.06–0.78
(12H, m, 4 × CH₂-alkyl chain) ppm; ¹³C NMR (75 MHz, CDCl₃, 25 °C): 164.2, 163.9, 163.3, 163.3, 147.2, 134.8, 134.2, 132.0, 131.5, 129.7, 129.3, 128.1, 126.6, 126.2, 124.6, 123.2, 123.0, 122.5, 122.3, 120.6, 120.0, 118.0, 116.2, 62.0, 60.2, 56.2, 44.3, 43.9, 38.1, 38.1, 37.8, 30.9, 30.7, 29.6, 28.8, 27.6, 27.9, 25.2, 24.1, 24.0, 23.1, 14.1, 10.7 and 10.6 ppm; IR-FT (KBr) ν/cm⁻¹: 3467, 2956, 2927, 2858, 1691, 1652, 1586, 1427, 1338, 1204, 870, 748; UV/vis (CH₂Cl₂), λ_max/nm (log ε): 431 (4.16), 637 (4.36); HR-MS (MALDI-TOF, dithranol): m/z = 713.349, [M⁺], calcd for C₄₅H₃₅N₆O₇: 713.383.

**Synthesis of N,N'-di(2-ethylhexyl)-1-(R)-2(acetylmethyl)pyrrolidinyl)-pereylene-3,4,9,10-tetraacrylo diimide (6).** 20 mg of 3 (0.03 mmol) were dissolved in 1 ml of acetic anhydride with a catalytic amount of H₂SO₄ (1 drop). The mixture was left, continuously stirred, at 90 °C for 2 h. The crude product was added over 200 ml of NaOH 1 M, extracted with CH₂Cl₂ and, after evaporation of the solvent, purified by Combiflash chromatography (0-5% of AcOEt in CH₂Cl₂). 17 mg of the desired product (75%) were obtained as a green powder.

¹¹H NMR (300 MHz, CDCl₃, 25 °C): 8.69 (1H, s, H-PDI), 8.63 (1H, d, J = 8.1 Hz, H-PDI), 8.62 (1H, d, J = 8.0 Hz, H-PDI), 8.52–8.41 (3H, m, 3 × H-PDI), 8.11 (1H, d, J = 8.1 Hz, H-PDI), 4.72 (1H, br s, CH₃N-pyrrolidine), 4.51 (2H, d, J = 3.93 Hz, CH₂O), 4.23–4.05 (4H, m, 2 × CH₂-N-alkyl chain), 3.78–3.68 (1H, m, CH₂N-pyrrolidine), 2.42–2.32 (2H, m, CH₂PDI), 2.17 (3H, s, CH₃), C=O), 2.11–1.88 (4H, m, CH₂-PDI + 2 × CH-alkyl chain) 1.50–1.24 (16H, m, 8 × CH₂-alkyl chain) and 1.01–0.84 (12H, m, 4 × CH₂-alkyl chain) ppm; ¹³C NMR (75 MHz, CDCl₃, 25 °C): 170.9, 164.3, 164.1, 147.8, 135.9, 135.2, 133.2, 131.3, 129.2, 129.1, 127.6, 127.5, 124.6, 124.0, 123.9, 123.3, 122.9, 122.6, 122.1, 121.0, 119.8, 118.9, 65.3, 57.5, 56.4, 44.5, 38.1, 31.0, 29.1, 28.9, 25.4, 24.3, 23.2, 21.0, 14.3, 10.9, 10.8; IR-FT (KBr) 2956, 2927, 2857, 1744, 1693, 1654, 1587, 1419, 1336, 1240, 808, 748 ν/cm⁻¹; UV/vis (CH₂Cl₂), λ_max/nm (log ε): 332 (3.80), 430 (4.17), 624 (4.36); HR-MS (MALDI-TOF, dithranol): m/z = 755.385, [M⁺], calcd for C₄₅H₃₅N₆O₇: 755.393.

**Synthesis of N,N'-di(2-ethylhexyl)-1-(R)-2(azafullereencarboxyl methyl)-pyrrolidinyl)-pereylene-3,4,9,10-tetraacrylo diimide (2).** Over a suspension of 2(azafullerenyl)acetic acid 6 (20 mg, 0.026 mmol), 3 (19 mg, 0.026 mmol) and DMAP (2.5 mg, 0.021 mmol) in dry dichloromethane (20 mL) at 0 °C under N₂, EDCI (15 mg, 0.078 mmol) was added and the mixture was left stirring at r.t. for 72 h. Then, the solvent was evaporated; the residue was then re-dissolved in o-dichlorobenzene (25 mL) and passed through a silica column chromatograph (toluene-toluene-ethyl acetate 9:1). The first green fraction was collected and further purified in preparative HPLC (bucky-prep, toluene, 10 ml min⁻¹. R.t. = 18.6 min) yielding 1 as green dust (3 mg, 8%). ¹¹H NMR (300 MHz, CDCl₃, 25 °C): 9.19 (1H, s, H-PDI), 8.69 (1H, d, J = 8.1 Hz, H-PDI), 8.59 (1H, d, J = 8.0 Hz, H-PDI), 8.44–8.35 (4H, m, 4 × H-PDI), 5.21–5.27 (2H, m, CH₂N-pyrrolidine + CH₂O), 4.87–4.77 (1H, m, CH₂N-pyrrolidine), 4.71 (1H, d, J = 16.2 Hz, O₂C-CH₂-N₁, CH₂N-pyrrolidine), 4.63 (1H, d, J = 16.2 Hz, O₂C-CH₂-N₁, CH₂N-pyrrolidine + NCH-CH₃-pyrrolidine + CH₂O), 1.48–1.22 (16H, m, 8 × CH₂-alkyl chain) and 1.02–0.80 (12H, m, 4 × CH₂-alkyl chain) ppm; ¹³C NMR (75 MHz, CDCl₃, 25 °C): 169.5, 164.5, 164.3, 164.1, 154.7, 154.8, 145.7, 147.8, 147.6, 147.5, 147.4, 147.1, 147.0, 146.7, 146.6, 146.5, 146.4, 146.3, 145.9, 145.8, 145.7, 145.1, 145.0, 144.8, 144.6, 144.3, 145.8, 143.6, 143.5, 142.7, 142.1, 141.7, 141.6, 141.1, 140.9, 140.8, 140.6, 139.4, 139.2, 137.0, 136.9, 135.8, 135.2, 134.2, 133.7, 133.6, 131.6, 131.1, 129.4, 129.0, 127.9, 127.6, 124.8, 124.3, 124.1, 123.9, 123.8, 123.6, 123.0, 122.4, 122.0, 121.0, 120.0, 119.2, 78.4, 68.4, 57.4, 57.1, 46.9, 44.5, 43.3, 43.7, 39.9, 39.8, 29.8, 29.1, 28.9, 28.8, 28.7, 25.3, 24.2, 23.3, 23.2, 14.3, 10.9 and 10.8 ppm; IR-FT (KBr) ν/cm⁻¹: 3425, 2953, 2925, 2856, 1747, 1694, 1656, 1588, 1421, 1334, 1242, 1185, 808, 748, 525; UV/vis (CH₂Cl₂), λ_max/nm (log ε): 321 (4.59), 431 (4.27), 632 (4.37); HR-MS (MALDI-TOF, dithranol): m/z = 1476.463, [M⁺], calcd for C₁₀₈H₇₃N₃O₁₂: 1476.389.
Conclusions

We have synthesized for the first time a dyad where a perylene-diimide unit is connected to C59N. Taking advantage of the electron donor character of the mono pyrrolidinyl PDI derivative synthesised, the PDI-C59N dyad undergoes efficient intramolecular photoinduced electron transfer to afford a 400 ps-lived CS state in PhCN. PDI-C60 has also been synthesised, as a reference compound, affording a 3 times shorter CSS lifetime than the PDI-C59N dyad to address the influence of the nitrogen in the photoinduced electron-transfer process. The present results have significant implications for the design of organic solar cells based on covalent donor–acceptor systems using C59N as the acceptor and shows that the longer-lived charge-separated states can be attained using C59N systems instead of C60 systems.
