Trinuclear (aminonitrone)ZnII complexes as key intermediates in zinc(II)-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles†

Dmitrii S. Bolotin,† Mikhail V. Il’in,† Alexander S. Novikov,† Nadezhda A. Bokach,† Vitalii V. Suslonov† and Vadim Yu. Kukushkin*†

Aliphatic and aromatic amidoximes R(CN)=NOH (R = Et, Bu, Ph, o-CIC6H4) react with Zn(OAc)2-2H2O in Me2CO giving [Zn(OAc)2(R(CN)=NOH)]2 complexes bearing N-bound amidoximes, which are involved in a moderate strength (7.3–11.9 kcal mol−1 by the DFT calculations) intramolecular resonance-assisted hydrogen bonding between the oxime HO group and the oxo group of the acetate ligand. The complexes [Zn(OAc)2(RCN)=NOH]2 react with excess Zn(OTf)2 in acetone accomplishing trinuclear species [Zn3(µ2-OAc)(µ2-RCN)=N(H)O4(H2O)2]4+(OTf)4 featuring both O-ligated amidoximes—stabilized in the aminonitrone tautomeric form—and bridging acetate ligands. The aminonitrone trinuclear species were also prepared directly via the reaction of the amidoximes with Zn(OTf)2 in EtOAc; ethyl acetate in this reaction plays the role of the acetate donor and OAc− is generated in situ via ZnII-mediated hydrolysis of EtOAc. Although [Zn(OAc)2(R(CN)=NOH)]2 are inactive toward dimethylcyanamide, the [Zn3(µ2-OAc)(µ2-RCN)=N(H)O4(H2O)2]4+(OTf)4 complexes readily react with Me2NCN giving, as a result of ZnII-mediated amidoxime–cyanamide coupling, the O-carbamidine amine complexes [Zn(OTf)2(RCN)=NOC(NMe2)=NH3]. All synthesized compounds were characterized by HRESI-MS, FTIR, 1H-, CP-MAS TOSS 13C{1H}-, and 13C{1H} NMR, and additionally by single-crystal X-ray diffraction for eight different types of non-covalent interactions in the obtained solid-state structures were studied by DFT calculations (M06-2X/6-311+G(d,p) level of theory) and topological analysis of the electron density distribution within the formalism of Bader’s theory (QTAIM method).

Introduction

The zinc(II)-mediated reaction between amidoximes and nitriles1 is among the most facile and expedient routes for the synthesis of 1,2,4-oxadiazoles—a class of heterocycles that exhibit a wide range of biomedical2 (e.g., antibacterial,3 antioxidant,4 antimalarial,5 anticancer,6 anticonvulsant,7 immuno-modulating8 and antihistaminic9) properties. These ring systems also act as active antihypertensive agents,10 selective inhibitors of 11β-hydroxysteroid dehydrogenase,11 dopamine D3 receptor ligands,12 glycogen phosphorylase inhibitors,13 and elecive agonists of free fatty acid receptor,14 and serve as useful precursors for materials science for mastering liquid crystals,15 nanoporous networks,16 and insensitive energetic materials.17

Recent synthetic works1,18 helped to obtain some data partially explaining the mechanism of heterocyclization. In particular, intermediates A and B (Scheme 1) in the reaction between R2NCN and R’(NH2)2C=NOH in the presence of zinc(II) in undried EtOAc were trapped and identified. These data allowed the assumption that the overall reaction starts from the ZnII-mediated amidoxime–nitrile coupling. However, black-boxed intermediate zinc(II) complexes featuring coordinated amidoximes and/or nitriles were neither isolated/characterized nor identified in situ by physicochemical methods.

Being interested in understanding the detailed mechanism of ZnII-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles1,16,18 and in further development of coordination chemistry of amidoximes (= aminonitrone) (for our review on this subject see ref. 19), we synthesized novel zinc(II) species featuring amidoximes and studied their reactivity toward

Me$_2$NCN as a representative of cyanamides. The main idea of this work was to obtain experimental data fully explaining the mechanism of zinc(II)-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles to provide a solid background for rational choice of reactants and reaction conditions.

The scenario of this study was as follows. Firstly, we synthesized zinc(II) amidoxime species and determined ligand coordination patterns (amidoxime and aminonitrone forms) and verified the structures of these complexes both experimentally and theoretically. Secondly, we studied the reactivity of the (amidoxime)Zn$^{II}$ and (aminonitrone)Zn$^{II}$ complexes toward Me$_2$NCN as a model cyanamide substrate. Based on all these data, thirdly, described the mechanism of zinc(II)-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles. All the obtained data along with the corresponding discussions are consistently disclosed in sections that follow.

Results and discussion

Generation of zinc(II) amidoxime and aminonitrone complexes

As starting materials for the generation of zinc(II) amidoxime and aminonitrone complexes we used the aromatic and aliphatic amidoximes RC(NH$_2$) = NOH (R = Ph 1a, o-ClC$_6$H$_4$ 1b, Et 1c, Bu 1d) and, as sources of zinc(II), the salts Zn(OAc)$_2$ and Zn(OTf)$_2$. We also applied Me$_2$CO and EtOAc as solvents in our synthetic experiments to understand the mysterious effect of ethyl acetate on the facilitation of the Zn$^{II}$-mediated reaction.

We started our experiments under conditions, which were applied for synthetically optimized Zn$^{II}$-mediated amidoxime–cyanamide coupling. When undried EtOAc was employed as a solvent in the reaction between 1a-d and Zn(OAc)$_2$ (Scheme 2, c2), we observed the generation of trinuclear complexes [3a-d][O Tf]$_4$. We varied molar ratios between 1a-d and Zn(OAc)$_2$ from 1:1 to 6:1, including 2:1, and found that the trinuclear complexes are formed in all these combinations. The highest yields of [3a-d][O Tf]$_4$ (70–87%) were achieved when the molar ratio between 1a-d and Zn(OAc)$_2$ was 4:3 and the reaction mixture was refluxed for 30 min in EtOAc (C2). We believe that in [3a-d][O Tf]$_4$, two bridging OAc$^-$ ligands are derived from Zn$^{II}$-mediated hydrolysis of EtOAc; a relevant metal-mediated hydrolysis of ethyl acetate has previously been repeatedly reported (see, for example, ref. 20).

Concurrently, treatment of 1a-d with Zn(OTf)$_2$ in a molar ratio 2:1 in acetone either at RT or 50 °C for 1 day gives a broad spectrum of products that we failed to separate. After keeping the reaction mixture for 1 week at 20–25 °C we observed the formation of [1a-dH][O Tf] in the solution along with some amount of zinc-containing precipitate.

We assumed that the presence of acetate favors the generation of the trinuclear complexes. Accordingly, 1a-d were treated with Zn(OAc)$_2$·2H$_2$O in a molar ratio 2:1 in acetone at 50 °C and we observed the fast (5 min) formation of 2a-d that were isolated in 75–82% yields (Scheme 2, a2). Complexes 2a-d were easily transformed into the corresponding [3a-d][O Tf]$_4$ when 2a-d reacted with 2 equiv. of Zn(OAc)$_2$ and 2 equiv. of 1a-d in undried acetone for 5 min at 50 °C (b2). The reverse process—which includes the transformation of [3a-d][O Tf]$_4$ to 2a-d—was not realized and the addition of the corresponding amidoxime (2 equiv.) and NaOAc (4 equiv.) to [3a-d][O Tf]$_4$ in acetone (5 min, 50 °C or 1 d, RT) led to amorphous zinc hydroxides and [1a-dH][O Ac].

Zinc(II)-mediated amidoxime–cyanamide coupling

In order to study the reactivity of the zinc(II)-bound oximes, we reacted complexes 2a-d and [3a-d][O Tf]$_4$ with dimethylcyanamide as a model nitrile substrate. When complexes [3a-d][O Tf]$_4$ were treated with 4 equiv. of Me$_2$NCN (EtOAc, RT, 3 h), the reaction yielded either imino complexes [4a-c(OTf)][OTf]$_3$ (R = Ph, o-ClC$_6$H$_4$ Et; Scheme 2, d2), or iminium salt [5d][OTf] (R = Bu; d2) in excellent (93–98%) yields. Complex [4d(OTf)]$_3$ was not obtained due to the steric hindrance of the bulky Bu group, which precluded the formation of the chelated complex and gave only uncomplexed [5d][OTf]. Imino complexes [4a-c(OTf)]$_3$ and salt [5d][OTf] were also generated by the direct reaction of 1a-d with Me$_2$NCN and Zn(OAc)$_2$ (EtOAc, RT, 3 h; c2). The yields of [4a-c(OTf)]$_3$ and [5d][OTf] obtained via route e2 are comparable with the corresponding overall yields determined for routes c2 and d2 (approx. 70–80%). Complexes 2a-d do not react with Me$_2$NCN at RT even for 24 h and a mixture of yet unidentified products was formed when the reaction was attempted at 50 °C for 3 h.

In our previous study, we demonstrated that substituted cyanamides and nitriles RCN (R = Alk, Ar, NR$_2$) are involved in the coupling with amidoximes in the presence of ZnCl$_2$ achieving the complexes [ZnCl$_2$·N(H)–C(R)ONC(NH$_3$)R$^3$] and this reaction is metal-mediated. Herein, we demonstrate that aminonitrone trinuclear species [3a-d][O Tf]$_4$ can also be involved in the zinc(II)-mediated coupling with Me$_2$NCN and (aminonitrone)Zn$^{II}$ complexes, viz. [3a-d][O Tf]$_4$, serve as key intermediates of the coupling.

Our observations provide a background for a deeper understanding of the mechanism of Zn$^{II}$-mediated amidoxime–cyanamide coupling. Insofar as 2a-d and [3a-d][O Tf]$_4$ demonstrated different reactivities toward Me$_2$NCN, one can assume a strong effect of the coordination pattern of the amidoxime on the reaction. Thus, in 2a-d, the N-coordinated amidoxime—which
is involved in the formation of intramolecular resonance-assisted hydrogen bonding (RAHB; for recent works on this type of hydrogen bonding see ref. 21) between the oxime HO group and the oxo group of the acetate ligand—does not react with Me₂NCN. In [3a-d][OTf]₄, O-coordinated amidoxime in its aminonitrone form reacted with Me₂NCN under mild conditions (RT, 3 h). The latter observation is in agreement with the theoretical calculation data, which demonstrated that oxime–nitrile coupling proceeds via the aminonitrone form of the nucleophile. 22

Analytical and spectroscopy data

Complexes 2a–d, [3a-d][OTf]₄, [4a-c(OTf)₂], and salts [5a-d][OTf] gave satisfactory C, H, and N elemental analysis results for the proposed formulas, and these species were also characterized by high-resolution ESI-MS, FTIR, ¹H, and CP-MAS TOSS ¹³C{¹H} NMR spectroscopy (for poorly soluble 2a–d, [3a-d][OTf]₄, and [5d][OTf]) or ¹³C{¹H} NMR spectroscopy (for [4a-c(OTf)] and [5a-c][OTf] exhibiting sufficient solubility) and additionally by single-crystal X-ray diffraction for eight species (2a–c, [3a][OTf]₄, [4b][OTf][EtOH][OTf][OTf], [4c][OTf]₂, [5a][OTf], and [5d][OTf]).

For a detailed description of the characterization see the ESI.† Briefly, the IR spectra of 2a–d, [3a-d][OTf]₄, and [4a-c(OTf)₂], exhibit one ν(C=N) band in the range 1678–1638 cm⁻¹, which is specific to amidoximes. ¹H The spectra of 2a–d and [3a-d][OTf]₄ also display three strong to very strong bands in the region 1608–1340 cm⁻¹ from the ν(C=O) of the ligated acetate group. A characteristic feature of the ¹H NMR spectra of 2a–d and [3a-d][OTf]₄ recorded in (CD₃)₂CO is the absence of the OH and ONH signals due to a fast exchange with water protons. Another feature is the availability of broad singlets attributed to the NH signals at 6.40–5.29 ppm (for 2a–d) and 8.48–7.93 ppm (for [3a-d][OTf]₄). The low-field shift of the signal in the spectra of [3a-d][OTf]₄ is probably due to the positive charge on the HNCNH₂ moiety provided by the stabilization of 1a–d ligands in the aminonitrone form.

X-ray structure determination, QTAIM and NBO analysis of the bonding

(i) The structures of the trinuclear complexes and aminonitrone coordination pattern. In the molecular structure of trinuclear [3a][OTf]₄, the coordination polyhedra of the zinc(II) centers display typical octahedral geometries (Fig. 1). All bond angles around the zinc(II) centers range from 73.29(16) to 105.95(17)°, the Zn–O [1.944(4)–2.1460(4) Å] and N(2)–C(1) [1.319(10)–1.330(8) Å] bonds are normal single bonds, 23 whereas the O(1)–N(sp²) distances [1.344(7)–1.357(7) Å] are shorter than the usual O–N(sp²) bonds and typical for O-ligated amidoximes in the aminonitrone form. ¹H The N(1)–C(1) distance values [1.298(8)–1.309(8) Å] indicate an intermediate order between typical single and double bonds, 23 which reflects the amide character of these bonds. The carbamidoxime groups are in the Z-configuration.

The intermolecular H-bonds are between the aminonitrone NH atom and the O atom of one of the triflate [N–O 2.749–2.789 Å; N–H–O 155.11–167.27°] Hydrogen bonds between the amide H atoms and the triflate O atoms and between the ligated H₂O and the triflate counter-ions were observed. It is noteworthy
that trinuclear complexes bearing bridging carboxylate ligands linking the three zinc centers in the \([\text{Zn}(\mu_2-O_2CR)\text{Zn}(\mu_2-O_2CR)\text{Zn}] \) (R = Me, Ph) moieties are known (for recent examples see ref. 24).

Amidoximes and their deprotonated forms possess three nucleophilic centers, viz. two N- and one O atom, therefore several types of coordination modes for these ligands can be realized. In our recent review,19 we analyzed the existing data on amidoxime coordination, verified nine patterns, and led to the conclusion that N-binding (as in \(2a–d\)) is the conventional coordination pattern.

The binding in the aminonitrone form, viz. \([M]\{\text{ON}(\text{H})\text{Q}C(\text{NR}_2)\text{R}^0\}\) or \([M]_2\{\mu_2-\text{ON}(\text{H})\text{Q}C(\text{NR}_2)\text{R}^0\}\) (Fig. 2) lesser common.

If the former type (A) of coordination was documented for UIV,25 PuIV,26 GeIV,19 SnIV,19 and FeIII 19,27 species, the latter type (B)—which we observed in \(3a–d\)(OTf)\(~4\)—is substantially less abundant and it was previously observed only for a molybdenum(VI) center.19,28 The difference in bonding pattern can be rationalized by the application of Pearson’s HSAB principle29 and charge considerations. Accordingly, the aminonitrone form coordinates to the harder and highly charged \([\text{Zn}(\text{OAc})_2]^{2+}\) moiety via a “hard” and negatively charged oxygen center, whereas neutral amidoximes tend to ligate to the neutral \(\text{Zn}(\text{OAc})_2\) species, as in \(2a–d\), via a relatively “soft” nitrogen center. An additional stabilization of \(2a–d\) by resonance-assisted hydrogen bonding (see below) should be taken into account.

(ii) The structures of monomeric \(2a–c\) involving resonance-assisted hydrogen bonding. In the molecular structures of \(2a–c\), the coordination polyhedra exhibit a distorted tetrahedral geometry (Fig. 3). All bond angles around the Zn(II) center range from 93.58(5) to 122.11(7)°. The Zn–O distances [1.9538(19)–1.9975(19) Å] are specific for the (acetate)\(\text{Zn}^{\text{II}}\) bonds.30 The Zn–N bond lengths \([1.9890(17)–2.0043(18) \text{ Å}]\) exhibit values characteristic for (oxime)\(\text{Zn}^{\text{II}}\) bonds.30 The O(1)–N(2) distances \([1.414(12)–1.425(2) \text{ Å}]\) are typical for \(N\)-ligated amidoximes.19 The N(2)–C(1) \([1.334(2)–1.342(4) \text{ Å}]\) and O(1)–C(2) \([1.328(2)–1.366(4) \text{ Å}]\) bonds are normal single bonds.23

The N(1)–C(1) distances \([1.296(4)–1.3042(18) \text{ Å}]\) indicate an intermediate order between typical single and double bonds,23 which reflects the amide character of these bonds. The carbamidoxime groups are in the \(Z\)-configuration.

Zinc(II) complexes with terminal \(N\)-coordinated amidoximes, are known,19 while the previously reported complexes comprise bidentately coordinated ligands in which at least one coordinating group is an \(N\)-coordinated amidoxime moiety (Fig. 4, \(C\)).31,19,30,31,32,33 Our complexes \(2a–d\) are the first examples of \(\text{Zn}^{\text{II}}\)-complexes bearing monodentately \(N\)-coordinated amidoxime, but one should take into account that this binding mode is rather specific as it is supported by RAHB (Fig. 4, \(D\)).
The topological analysis of the electron density distribution within the formalism of Bader’s theory (QTAIM method)\textsuperscript{34} for 2a–c (this approach has already been successfully used by us in studies of the non-covalent interactions and properties of coordination bonds in various transition metal complexes\textsuperscript{22,35}) demonstrates the presence of appropriate bond critical points (BCPs) (3, \( \nabla^2 \rho \)) for intramolecular RAHB O–H \( \cdots \) O in 2a–c (Fig. 5). The low magnitude of the electron density, positive values of the Laplacian, and zero or close to zero positive energy density in these BCPs are typical for hydrogen bonding (Table S3, ESI\textsuperscript{†}).

The balance between the Lagrangian kinetic energy \( G(\mathbf{r}) \) and potential energy density \( V(\mathbf{r}) \) at these BCPs (\( -G(\mathbf{r})/V(\mathbf{r}) \approx 1 \)) reveals the purely non-covalent nature of these interactions. The strength of O–H \( \cdots \) O contacts (7.3–11.9 kcal mol\textsuperscript{−1}) corresponds to moderate hydrogen bonds following the classification of Jeffrey (‘‘weak’’ HBs: <4 kcal mol\textsuperscript{−1}, ‘‘moderate’’ HBs: 4–15 kcal mol\textsuperscript{−1}, ‘‘strong’’ HBs: 15–40 kcal mol\textsuperscript{−1}).\textsuperscript{36} The negligible values of the Wiberg bond indices for these contacts (0.01–0.04) computed by using the natural bond orbital (NBO) partitioning scheme additionally confirm the electrostatic nature of these non-covalent interactions. The electron-density delocalization in RAHB-involved 7-membered quasi-heterocyclic fragments in 2a–c has been estimated by the analysis of Wiberg bond indices (WI) for appropriate contacts (Table S4, ESI\textsuperscript{†}). The WI for O–C and C–O contacts in 2a–c (1.29–1.55) indicate that these bonds are significantly involved in the conjugation. For more detailed information about our DFT calculations see the ESI.\textsuperscript{†}

(iii) The structures of the coupling products. In the molecular structures of [4b(OTf)(EtOH)][OTf] and [4c(OTf)\textsubscript{2}], the coordination polyhedra of the zinc(u) complexes display a typical distorted octahedral geometry (Fig. 6 and 7). All bond angles around the zinc(u) centers range from 75.44(10) to 119.93(16)°. The Zn–N(b) bond lengths [2.079(4)–2.121(3) Å] exhibit values characteristic for (oxime)Zn\textsuperscript{II} bonds,\textsuperscript{30a} whereas the Zn–N(b) distances [1.944(4)–1.961(3) Å] are usual for (imine)Zn\textsuperscript{II} complexes.\textsuperscript{30a} The Zn–O(2) bond lengths [2.507(4)–2.597(4) Å] are longer than the normal single bonds thus indicating their ionic character,\textsuperscript{30a} the N(2)–C(1) [1.317(7)–1.336(4) Å], N(4)–C(2) [1.330(6)–1.349(6) Å], and N(4)–C(3/4) [1.454(6)–1.466(4) Å] bonds are typical single bonds.\textsuperscript{23} The N(1)–C(1) distances and the N(3)–C(2) bond lengths [1.296(4)–1.309(4) Å] indicate an intermediate order between typical single and double bonds,\textsuperscript{23} which reflects the amide character of these bonds. The O(1)–N(1) distances [1.438(5)–1.451(3) Å] are longer than usual O–N\textsuperscript{sp2} bonds, which is specific for O-imidoylamidoximes.\textsuperscript{1a} The carbamidoxime groups of both complexes are in the Z-configuration. In the crystal structures of

Fig. 8 Contour line diagram of the Laplacian distribution $\nabla^2 \rho(r)$, bond paths and selected zero-flux surfaces for contacts Zn–O and Zn–N in $[4c(\text{OTf})_2]$; Bond critical points (3, –1) are shown in blue, nuclear critical points (3, –3) in pale brown, and ring critical points (3, +1) in orange, length unit – Å.

$[4b(\text{OTf})(\text{EtOH})]\text{(OTf)}$ and $[4c(\text{OTf})_2]$, hydrogen bonds between the amide H atoms and the triflate O atoms were observed. The structure of $[4b(\text{OTf})(\text{EtOH})]\text{(OTf)}$ includes one coordinated EtOH molecule that can be derived from the Zn(II)-mediated cleavage of EtOAc. This additionally confirms the occurrence of the Zn$^{II}$-mediated hydrolysis of EtOAc giving AcOH and ETOH.

In $[4c(\text{OTf})_2]$, the QTAIM analysis reveals the presence of two BCPs for Zn–O and four BCPs for Zn–N contacts (Fig. 8). The properties of electron density in BCPs for Zn–N contacts are typical for ordinary coordination bonds (the $r(r)$ and $\nabla^2 \rho(r)$ values are positive and relatively high; the $H_b$ values are significantly negative; the $-G(r)/V(r)$ $\ll$ 1; Wiberg bond indices for these contacts are noticeable), whereas Zn–O contacts can be classified as non-covalent close shell interactions with some contribution of the covalent component (for more detailed information see the ESI†).

(iv) The structures of the O-iminoacylated oximes. The structures are similar to those reported previously$^{1a,18}$ and a detailed description of the molecular structures of $[5a(\text{OTf})]$ and $[5d(\text{OTf})]$ is given in the ESI.$^*$

Zinc(II)-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles

In this work, we succeeded in isolating and identifying zinc(II) complexes featuring amidoximes and aminonitrones and studied the reaction of these (amidoxime/aminnitronen)Zn$^{II}$ complexes with Me$_2$NCN. All accumulated data combined with those from our previous study$^{18}$ on metal-free heterocyclization of amidinium salts $[5]^+$ allowed the formulation of the detailed mechanism of zinc(II)-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles that efficiently proceeds in undried ethyl acetate.

Firstly, complexes 2a–d are formed via coordination of both an amidoxime and AcO$^-$ to the zinc(II) center (Scheme 3, b3 and d3). Acetate is generated via the zinc(II)-mediated hydrolysis of EtOAc and this explains why the reaction occurs so easily namely in ethyl acetate (c3). Amidoxime complexes 2a–d are inactive toward dimethylcyanamide, whereas aminonitrene complexes $[3a-d]^+$—which are formed from 2a–d with excess zinc(II) (e3 and f3)—react with Me$_2$NCN giving imino

Scheme 3  Mechanism of the zinc(II)-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles.
species [4a–c] and [3a–d] toward the coupling with Me2NCN is surprising. The observed high reactivity of the trinuclear complexes can be further explored in at least two directions: (i) nitrones, as allyl anion type dipoles, are involved in cycloaddition reactions with various dipolarophiles. Although amidoximes exist in tautomeric equilibrium with their amonitrione form RCONH2→N+(H)O−, amonitrione reactivity (e.g. toward cycloaddition) has never been observed in the past. The obtained amonitrione trinuclear complexes represent available reactants for the inverse electron demand cycloaddition (type III in Sustman’s classification), when the reaction involves complexed dipole and uncoordinated dipolarophile; (ii) many organic reactions involving polynuclear metal species proceed via simultaneous coordination of two reactants to the adjacent metal centers, which, via the so-called “two-metal-mechanism”, couples intramolecularly. One can assume that substrates with donor centers could split the [Zn2+]3(μ2-ON(H)=C(NR3)R′) bridge by their ligation to a zinc(II) center followed by intramolecular coupling with amonitrones leading to novel organic species. All works in these two directions are underway in our group.

Concluding remarks

In this work, we succeeded in generating, isolating, and fully characterizing the trinuclear zinc(II) species [3a–d] toward the coupling with Me2NCN, which most likely serve as key intermediates in the Zn(II)-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles in EtOAc. The amidoxime ligands in [3a–d] are stabilized in their amonitrione form, RC(NH2)=N+(H)O−, and they act as μ2-ligands being coordinated through the O atom. Before our experiments, this type of coordination was unknown for amidoxime zinc(II) complexes and this ligation pattern was observed only at a molybdenum(vi) center.

All accumulated reactivity data, combined with those from our previous study, on metal-free heterocyclization of amidinium salts, allowed the formulation of the detailed mechanism of the zinc(II)-mediated generation of 1,2,4-oxadiazoles from amidoximes and nitriles and the explanation of the effect of undried ethyl acetate on facilitation of the heterocyclization (Scheme 3). It is now clear that the overall reaction consists of four main steps namely the acetate-promoted formation of the trinuclear complexes, amidoxime–nitrile coupling, acid driven decoordination, and, eventually, the heterocyclization. All these data allowed the rational choice of the reactants and further tuning of the reaction conditions. It is noteworthy that although for a while we are satisfied with improving the synthesis of 1,2,4-oxadiazoles with stoichiometric amounts of zinc(II), our distant goal is to find out a catalytic system for the preparation of 1,2,4-oxadiazoles and we are currently testing appropriate catalytic systems.

One more issue requires additional attention. Zinc(II) centers belong to the category of kinetically labile metal centers when ambidentate or, in general, ligands with multiple donor centers are subject to facile linkage isomerization giving various coordination pattern species. In this respect, the different reactivity of 2a–d and 3a–d toward the coupling with Me2NCN is surprising. The observed high reactivity of the trinuclear complexes can be further explored in at least two directions: (i) nitrones, as allyl anion type dipoles, are involved in cycloaddition reactions with various dipolarophiles. Although amidoximes exist in tautomeric equilibrium with their amonitrione form RCONH2→N+(H)O−, amonitrione reactivity (e.g. toward cycloaddition) has never been observed in the past. The obtained amonitrione trinuclear complexes represent available reactants for the inverse electron demand cycloaddition (type III in Sustman’s classification), when the reaction involves complexed dipole and uncoordinated dipolarophile; (ii) many organic reactions involving polynuclear metal species proceed via simultaneous coordination of two reactants to the adjacent metal centers, which, via the so-called “two-metal-mechanism”, couples intramolecularly. One can assume that substrates with donor centers could split the [Zn2+]3(μ2-ON(H)=C(NR3)R′) bridge by their ligation to a zinc(II) center followed by intramolecular coupling with amonitrones leading to novel organic species. All works in these two directions are underway in our group.

Experimental section

Materials and instrumentation

Solvents were obtained from commercial sources and used as received. All of the syntheses were conducted in an air atmosphere. Amidoximes 1a–d were synthesized according to the literature methods. Melting points were measured on a Stuart SMP30 apparatus in capillaries and were not corrected. Microanalyses (C, H, N) were carried out on a Euro EA3028-HT instrument. Electrospray ionization mass-spectra were obtained on a Bruker microTOF spectrometer equipped with an electrospray ionization (ESI) source. The instrument was operated both in negative and positive ion modes in the m/z range 50–3000. The nebulizer gas flow was 0.4 bar and the drying gas flow was 4.0 L min−1. For HRESI, complexes were dissolved in MeOH. In the isotopic pattern, the most intensive peak is reported. Infrared spectra (4000–400 cm−1) were recorded on a Shimadzu IR Prestige-21 instrument in KBr pellets. 1H and 13C (1H) NMR spectra were measured on a Bruker Avance 400 at ambient temperature; residual solvent signals were used as the internal standard. Solid state CP-MAS TOSS 13C (1H) NMR spectra were measured on Bruker Avance III WB 400 with the magic angle spinning at 6 kHz frequency.

X-ray structure determination

The single-crystal X-ray diffraction experiment was carried out using Agilent Technologies “Xcalibur” and “Supernova” diffractometers with monochromated MoKα or CuKα radiation, respectively. The crystal was fixed on a micro mount, placed on the diffractometer and measured at a temperature of 100 K. The unit cell parameters and other summarized data are represented in Tables 1 and 2 (ESI†). The structure has been solved by using the Superflip41 structure solution program using charge flipping and refined using the ShelXL42 refinement.
incorporated in the OLEX2 program package. The hydrogen atoms were placed in calculated positions and were included in the refinement in the ‘riding’ model approximation. Empirical absorption correction was applied in the CrysAlisPro program complex using spherical harmonics, implemented in SCALE3 ABSPACK scaling algorithm. CCDC 1503999–1504006.

Computational details

The single point calculations based on the experimental X-ray geometries (quasi-solid-state approach) have been carried out at the DFT level of theory using the M06-2X functional (this functional was specifically developed to describe weak dispersion forces and non-covalent interactions) with the help of Gaussian-09 program package. The standard 6-311+G(d,p) basis sets have been used for all atoms. The topological analysis of the electron density distribution with the help of the atoms-in-molecules (QTAIM) method developed by Bader has been performed by using the Multiwfn program (version 3.3.7). The Wiberg bond indices (WI) were computed by using the natural bond orbital (NBO) partitioning scheme. The Cartesian atomic coordinates of model structures are presented in ESI, † Table S5.

Syntheses and characterization

Preparation of 2a–d. Powders of 1a–d (1 mmol) were added to a solution of Zn(OAc)2·2H2O (109.8 mg; 0.5 mmol) in acetone (6 mL) placed in a 10 mL round-bottomed flask. The solution was stirred for 5 min at 50 °C, then evaporated in vacuo at 50 °C. An oily residue was crystallized under chloroform (1.5 mL) with ultrasound treatment. The resulting precipitate was filtered off, and dried in air at 50 °C.

2a. Yield: 80% (182.3 mg). Mp: 145 °C (dec.). Anal. calcd for C18H23N2O4Zn: C, 37.43; H, 4.87; N, 12.29. Found: C, 37.28; H, 4.83; N, 12.28. HR-ESI-MAS (m/z): 240.9729 ([Zn(OAc)]2, calcd 240.9685), 424.9282 ([Zn2(OAc)]3, calcd 424.9213). IR (KBr, selected bands, cm−1): 3484(s), 3428(s), 3344(s–vs), 3218(s) v(C–H); 1672(vs) v(C=O). 1H NMR (CD3)2CO, δ: 6.40 (s, br, 2H, NH2), 2.30 (q, 2H, CH2), 1.92 (s, 3H, CH3), 1.16 (t, 3H, CH2). CP-MAS TOSS 13C{1H} NMR (δ): 182.47, 178.12 (CH3O2); 160.93 (C–N);
25.41 (CH₂CH₃); 22.98, 21.56 (CH₃CO₂); 12.85, 11.43 (CH₂CH₃). Crystals of 2c suitable for X-ray diffraction were obtained by slow evaporation of Me₃CO solution at RT in air.

2d. Yield: 78% (162.2 mg). Mp: 98 °C (dec.). Anal. calcd for C₁₉H₄₆N₈Cl₄F₁₂O₂₆S₄Zn₃: C, 25.42; H, 2.73; N, 6.59. Found: C, 25.60; H, 2.51; N, 6.84. HRESI-MS (MeOH, m/z): 292.9639 ([Zn(OAc)₂(C₂H₅NH₂)₂]⁺, calcd 292.9666), 404.9625 ([Zn(C₂H₅NH₂)₂(NO₂)₂]⁺, calcd 404.9672), 416.8932 ([Zn(OAc)₂(C₂H₅NH₂)₂(NO₂)]⁺, calcd 416.8982), 528.8937 ([Zn₂(OAc)₂(C₂H₅NH₂)₂(NO₂)]⁻, calcd 528.8997), 588.9144 ([Zn(OAc)₂(C₂H₅NH₂)₂(NO₂)]⁻, calcd 588.9209), 648.9352 ([Zn(OAc)₂(C₂H₅NH₂)₂(NO₂)]⁻, calcd 648.9421). HRESI-MS (m/z): 682.7972 ([Zn(OAc)₂(C₂H₅NH₂)₂(NO₂)]⁻, calcd 682.8064), 896.6801 ([Zn₂(OAc)₂(C₂H₅NH₂)₂(NO₂)]⁻, calcd 896.6773). IR (KBr, selected bands, cm⁻¹): 3422(s), 3314(w–m), 3234(s) ν(O–H) and ν(N–H); 1778(w), 1754(vs) ν(O–H) and ν(N–H); 1574(vs), 1438(s), 1406(s), 1350(m) ν(C–O); 1250(vs), 1174(vs) ν(S–O). 1H NMR (CD₃CO₂): 7.93 (s, br, 2H, NH₂), 7.68 [m, 1H, CH₂], 7.62 [m, 1H, CH], 7.52 [m, 2H, CH₂], 1.95 [3H, CH₃]. CP-MAS TOSS ¹³C{¹H} NMR (δ): 177.82 (CH₃CO₂), 152.40 (C–N); 130.61, 128.63, 124.60 (Ar); 119.31, 116.28 (CF₃); 23.48, 22.31, 21.36 (CH₃).

Preparation of [3a–d](OTf)₄. Route b2. Powders of 1a–d (1 mmol) were added to a stirred solution of the corresponding complexes 2a–d (0.5 mmol) and Zn(OTf)₂ (363.52 mg: 1 mmol) in acetonitrile (6 mL) placed in a 10 mL round-bottomed flask. The solution was stirred for 30 min on reflux, and then the solvent was evaporated in vacuo at 50 °C. For both routes, the oily residue that was formed was crystallized under chloroform (1.5 mL) with ultrasound treatment. The resulting precipitate was filtered off, and dried at 50 °C (route b2) or at 70 °C (route c) in air. The yields are given for route c. For route b2, the yields are 80–90% based on the corresponding 2a–d.

3a[OTf]₄. Yield: 87% (680 mg). Mp: 116 °C (dec.). Anal. calcd for C₁₉H₄₆N₈F₁₂O₂₆S₄Zn₃: C, 27.66; H, 3.22; N, 7.17. Found: C, 27.44; H, 2.99; N, 7.21. HRESI-MS (MeOH, m/z): 359.0067 ([Zn(OAc)₂(PhC(NH₂)₂)₂]⁺, calcd 359.0056), 335.0433 ([Zn(PhC(NH₂)₂)₂]⁺, calcd 335.0481), 382.9308 ([Zn(OAc)₂(PhC(NH₂)₂)₂]⁺, calcd 382.9372), 458.9737 ([Zn₂(OAc)₂(PhC(NH₂)₂)₂]⁻, calcd 458.9798), 519.9933 ([Zn₂(OAc)₂(PhC(NH₂)₂)₂]⁻, calcd 519.0001), 579.0156 ([Zn₂(OAc)₂(PhC(NH₂)₂)₂]⁻, calcd 579.0222). HRESI-MS (m/z): 646.8494 ([Zn(OTf)₂(PhC(NH₂)₂)₂]⁺, calcd 646.8483), 862.7197 ([Zn₂(OTf)₂(PhC(NH₂)₂)₂]⁻, calcd 862.7167). IR (KBr, selected bands, cm⁻¹): 3412(s), 3216(s) ν(O–H) and ν(N–H); 2968(w), 2868(w) ν(C–H); 1658(vs) ν(C–N); 1570(vs), 1448(s), 1404(s) ν(C–O); 1246(vs), 1174(vs) ν(S–O). 1H NMR (CD₃CO₂): 8.48 (s, br, 2H, NH₂), 7.83 [m, 1H, O–CH], 7.73 [t, br, 1H, p–CH], 7.62 (t, br, 2H, m–CH), 1.95 [3H, CH₃]. CP-MAS TOSS ¹³C{¹H} NMR (δ): 178.42 (CH₃CO₂), 157.59 (C–N); 133.77, 131.04, 127.15, 124.37 (Ar); 119.12 (CF₃); 26.10 (CH₃). Crystals of [3a][OTf]₄ suitable for X-ray diffraction were obtained by slow evaporation of Me₃CO solution at RT in air.

3b[OTf]₄. Yield: 73% (620.9 mg). Mp: 119 °C (dec.). Anal. calcd for C₁₉H₄₆N₈F₁₂O₂₆S₄Zn₃: C, 17.75; H, 3.68; N, 8.17. Found: C, 17.77; H, 3.46; N, 8.43. HRESI-MS (MeOH, m/z): 211.0127 ([Zn(OAc)₂(PhC(NH₂)₂)₂]⁺, calcd 211.0056), 239.0471 ([Zn(ETC(NH₂)₂)₂]⁺, calcd 239.0491), 334.9362 ([Zn₂(OAc)₂(ETC(NH₂)₂)₂]⁻, calcd 334.9372), 362.9773 ([Zn₂(OAc)₂(ETC(NH₂)₂)₂]⁻, calcd 362.9797), 422.9981 ([Zn₂(OAc)₂(ETC(NH₂)₂)₂]⁻, calcd 423.0009),
[3d][OTf]₄. Yield: 70% (519.1 mg). Mp: 73 °C (dec.). Anal. calc.: C₂₅H₂₄N₂O₇ (419.3815). HRESI MS (MeOH, m/z): 419.0386 (M²⁺, calcd 419.0386). Preparation of [4a–c][OTf]₄ and [5d][OTf]₄. Me₂NCN (161.0 µL; 2 mmol) was added to a stirred solution of [3a–c][OTf]₄ (0.5 mmol) in EtOAc (10 mL) (Scheme 2, route d2) or to a stirred solution of 1a–c (2 mmol) and Zn[OTf]₂ (363.5 mg; 1 mmol) in EtOAc (10 mL) (route e2). The solution was kept for 3 h at RT and then the resulting precipitate was filtered off, washed by three 1 mL portions of EtOAc, and dried at 50 °C. The yields are given for route e2. For route d2, the yields are 98% based on the corresponding [3a–c][OTf]₄. In the case of 1d (route e2) or [3d][OTf]₄ (route d2), the reaction results in the precipitation of [5d][OTf]₄ in 79% (route e2) or 98% (route d2) yields.

[4a(OTf)₂]. Yield: 76% (589.8 mg). Mp: 150 °C (dec.). Anal. calc.: C₃₂H₂₆N₄O₇ (589.8022). HRESI MS (MeOH, m/z): 589.8022 (M–OTf, calcd 589.8022). IR (KBr, selected bands, cm⁻¹): 3350 (s), 3056 (w), 2920 (w–m), 1645 (vs), 1578 (vs–m), 1490 (m–s), 1389 (s–m), 1294 (vs–m), 1182 (s–m), 1162 (s–m), 1045 (s–m), 771 (s–m), 747 (s–m). HRMS (S–TOF): m/z: 589.8022 (M⁰⁺, calcd 589.8022).
