Synthesis of \(\alpha\)-sulfonyloxyketones via iodosobenzene diacetate (PIDA)-mediated oxysulfonyloxylation of alkynes with sulfonic acids†

Yang Zhang,* Hua Tan and Weibing Liu†*

A simple yet powerful method to synthesize a variety of \(\alpha\)-sulfonyloxyketones has been developed. This novel method can be applied for the direct oxysulfonyloxylation of alkynes with sulfonic acids to access a variety of \(\alpha\)-sulfonyloxyketones. Compared to the reported methods for the application of PIDA, this study expands its application scope and uses it not only as the oxidant but also as the carrier of "O" to form the carbonyl group in the products. In addition, under the established conditions, this methodology not only exhibits a broad substrate scope but also demonstrates exclusive regioselectivity with substrates of 1,2-disubstituted internal alkynes.

In recent decades, due to their low toxicity, high stability, environmental-friendliness, easy availability, clean transformation and very useful oxidizing properties, hypervalent iodine compounds have attracted great interest from the chemical synthesis community and emerged as a useful alternative for a wide variety of organic transformations. To date, the existing studies have mainly focused on the oxidation reactions which use iodine(m) and iodine(v) compounds as substrates to replace highly toxic heavy-metal-based oxidants. Recently, the application scope of hypervalent iodine reagents has been expanded, and a dual role has emerged for iodine(m) and iodine(v) compounds in organic oxidation transformations which employ them not only as organic oxidants, but also as carriers of some organic functional groups, such as \(-O_2CR\), \(-CF_3\), \(-OTs\), \(-NR_2\), \(-C\equiv C\equiv R\), \(-N_3\) and \(-Ar\) in the "atom-transfer" oxidative coupling reactions that lead to the formation of new C–C and C–hetero bonds. However, reports involving the use of hypervalent iodine reagents as the “O” source of a carbonyl group are very rare to date. Since our protracted interest in the community of hypervalent iodine reagents involves oxidative reactions, in this report we will describe one approach that to the best of our knowledge has not been reported until now.

This study was started by using the model substrates phenylacetylene (1a) and \(p\)-toluenesulfonic acid (PTSA) (2a) to probe the feasibility of this reaction (Table 1). Initially, the reaction was performed with 1 equiv. of PIDA in 1,2-dichloroethane (DCE) at room temperature for 12, 24 and 36 h. We were satisfied to find that the desired product 1-oxo-1-phenylethyl \(p\)-toluenesulfonate 3aa, was obtained with a 39%, 54% and 54% yield, respectively (entries 1–3). These moderate yields motivated us to improve the yield of the desired product 3aa. On switching from DCE to other solvents like toluene, dioxane, CH\(_2\)CN, CH\(_3\)OH and Et\(_3\)N (entries 4–8), the best result was obtained in CH\(_2\)CN (80% yield) (entry 6). Intriguingly, the reaction performed poorly when the reaction was carried out at 70 °C, and the yield of the product 3aa decreased to 57% (entry 9). In contrast, a slight increase in the yield was obtained by varying the equivalents of PIDA from 1.0 to 1.3 (entry 10).

The scope of the reaction was investigated by varying the substrates of 1 and 2 under the established conditions (Scheme 2). Initially, the reaction of a variety of terminal ary lethynylenes bearing various substituents was investigated first.
It was found that the electronic properties of the substituents on the phenyl ring did not affect the yield too much. According to the results of the yields, terminal arylethylenes bearing electron-donating substituents (i.e., alkyl and methoxy) performed slightly better in this transformation than those bearing electron-withdrawing substituents (i.e., F, Br, and Cl), and produced the desired product in relatively high yields. For instance, terminal arylethylenes bearing electron-donating substituents, such as Me (1b), Et (1d), propyl (1e), ‘Bu (1f) and MeO (1j) produced the desired products 3ba, 3da, 3ea, 3fa and 3ja in good yields, while electron-withdrawing substituents, such as the F (1g) and Cl (1h) groups led to decreased yields. Also, we were disappointed to find that the position of a given substituent on the phenyl ring of terminal arylethylenes did impact the yield significantly, and para-substituted products were more favorable than ortho- and meta-substituted ones. For example, 1-bromo-2-ethynylbenzene (1i) produced 3ia with the lowest yield (59%). To our satisfaction, this conversion proceeded smoothly with high regioselectivity when 1,2-disubstituted internal alkynes like methyl 3-phenylpropiolate (1k) and 1-(pent-1-ynyl)benzene (1l) were used as the substrates and produced their corresponding product (3ka and 3la) with excellent yield. In order to further expand the scope of this protocol, several sulfonic acid derivatives like methanesulfonic acid (2b), ethanesulfonic acid (2c), phenylsulfonic acid (2d) and naphthalene sulfonic acid (2e) were used as substrates under the established conditions. The experimental results confirmed that all these aliphatic sulfonic acids and arylsulfonic acids are excellent partner of PTSA (2a), and all the tested reactions proceeded smoothly and produced their corresponding product with excellent yield (3ab: 87%, 3ac: 85%, 3ad: 82% and 3ae: 81%).

To clarify the source of oxygen in the generated carbonyl group in this work, we conducted two control experiments

*a* Reaction conditions: 1a (1.0 mmol), 2a (1.0 mmol), PIDA (1.0 equiv.), solvent (2.0 mL). *b* GC yield. *c* Reaction temperature: 0 °C. *d* PIDA: 1.3 equivalent.

Scheme 2  Exploring of the substrate scope (all reactions are carried out on a 2.0 mmol scale using CH3CN (2.0 mL) as the solvent and all the listed yields are isolated yield. The number in parentheses is the isolated yield of propiophenone 1a (10.0 mmol scale) after purification by column chromatography).
In involucres the direct nucleophilic oxysulfonyloxylation of mediate 6 which undergoes hydrolysis to produce the enol 5 of yields intermediate 7. Subsequently, the reduction elimination of 5 through the release of Phil leads to the formation of intermediate 6 which undergoes hydrolysis to produce the enol 7. Finally, the tautomeration of enol 8 liberates the stable α-sulfonyloxyketone 3aa. Alternatively, the reaction maybe begins with the combination of 1a with PIDA to activate the C–C triple bond to give electrophilic intermediate 8, which then reacts with the nucleophilic acetate anion to generate intermediate 9. The release of one molecule of acetate anion from intermediate 9 yields iodonium ylide 10. The following hydrolysis of the ylide 10 gives ketone intermediate 11. Then the nucleophilic attack of sulphonate anion on the electrophilic iodonium cation affords the final product α-sulfonyloxyketone 3aa.

In conclusion, we have developed a novel hypervalent iodonene(n)-promoted method for oxysulfonyloxylation of alkynes using sulfonic acids to access α-sulfonyloxyketones. Compared to the reported methods involving the application of PIDA, the present study expands the application scope of PIDA as an oxidant and O-source of carbonyl group. In general, this approach exhibited a broad substrate scope for the synthesis of α-sulfonyloxyketones under milder conditions. In addition, the easy availability of reactants as well as the use of simple oxidant and O-source makes the present method a useful new option for α-sulfonyloxyketone synthesis.
